Subject: **FEASIBILITY STUDY FOR FENTON'S REAGENT GAC REGENERATION AT MMR FACILITIES**	Issued By: Patricia de Groot CH2M HILL PROGRAM MANAGER

ITEM	REMARKS
1.0	**PURPOSE AND OBJECTIVE** The purpose of this feasibility study was to perform a preliminary assessment of regenerating spent granular activated carbon (GAC) on-site potentially without removing the spent GAC from the vessel utilizing the Fenton's reagent process. Currently, spent GAC from treatment systems used for removal of volatile organic compounds (specifically trichloroethene [TCE] and tetrachloroethene [PCE]) from groundwater at the Massachusetts Military Reservation (MMR) is shipped offsite for reactivation in a natural gas-fired kiln at high cost (currently $11,000 per 20,000-pound [lb] load of GAC) and with associated greenhouse gas emissions. If viable, the potential benefits of on-site regeneration with Fenton's reagent include: • Transformation of environmental contaminants into less toxic byproducts by oxidation. • Re-establishing the sorptive capacity of the GAC for the target chemicals to allow reuse of GAC, thereby increasing the useful life of the GAC and reducing treatment costs. • Eliminating or reducing the need for offsite transport and the thermal reactivation of GAC and its associated greenhouse gases. • Provides potential consistency with overall facility goals of improved sustainability.
2.0	**BACKGROUND** Historically, the Fenton's reagent process has been utilized in industrial applications for wastewater treatment. More recently, it has been used for in-situ soil and groundwater remediation applications. However, studies involving application of Fenton's reagent to GAC regeneration have only been recently done (see Section 9.0). As such, the use of the Fenton process for regeneration of GAC is in the developmental stage. Consequently, the sources of information for this technology used in this feasibility study are from the literature based on associated pilot and bench test studies. Due to the developmental stage of this technology, the results and conclusions of this feasibility study cannot be definitive, but may indicate the potential benefits and costs of this technology and may help determine if additional study and process development may be warranted.

ITEM	REMARKS
	The subsequent sections of the memo include the following: • Fenton Reagent Process Overview • Review of Past Studies and Key Findings • Proposed Fenton Reagent GAC Regeneration Process • Cost Estimates • Results and Conclusions
3.0	**FENTON REAGENT PROCESS OVERVIEW** The basic Fenton process is an iron-catalyzed oxidation reaction process using hydrogen peroxide (H_2O_2) as the oxidant. Fenton's Reagent is H_2O_2 applied at pH below 4 and in the presence of a ferrous iron (Fe^{+2}) catalyst to destroy organic contaminants through the process of oxidation. Sulfuric or hydrochloric acid can be used to adjust the pH. Iron can be added in a number of forms such as ferric sulfate, ferric chloride, ferric nitrate and ferrous sulfate. The reaction of Fe^{+2} with H_2O_2 produces a highly reactive hydroxide radical (OH•) that is a very strong oxidizing species as shown in the following reaction: $H_2O_2 + Fe^{+2} => Fe^{+3} + OH^- + OH•$ The acidic pH helps keep ferric iron (Fe^{+3}) in the solution until other species participating in the Fenton's Reagent process can react with the hydroxide radical including reduction of the Fe^{+3} back to Fe^{+2} with excess hydroxide radical. The regenerated Fe^{+2} can then be reused for hydroxide radical generation in a catalytic manner. The oxidizing power of the OH• radical is sufficient to degrade many organics (including volatile organic compounds (VOCs), chlorinated ethenes, pesticides, and semivolatile organic compounds) to reaction products such as carbon dioxide (CO_2), water, and hydrochloric acid (HCl). The OH• radical also reduces peroxide to oxide products, such as water, hydroxide, etc.
4.0	**REVIEW OF PAST STUDIES AND KEY FINDINGS** Bench scale and pilot studies involving application of Fenton's reagent to GAC regeneration have been recently done by the U.S. Environmental Protection Agency's (EPA) Office of Research and Development. Several related technical papers were reviewed for this feasibility study (see Reference List). The principal investigator for these studies was Scott Huling, EPA, Robert S. Kerr Environmental Research Center, Ada, OK. It is noted that EPA's testing was done in the context of MTBE adsorption on GAC and the subsequent regeneration of the GAC. MTBE is not as strongly adsorbed to GAC as PCE and TCE and therefore MTBE would be easier to desorb, but the process should still be effective to some degree on these other compounds.

ITEM	REMARKS

The information obtained from the literature was augmented with additional information provided by the EPA in a presentation that the EPA made on this technology in 2007 to CH2M HILL based on pilot studies conducted at the University of Arizona's (U of A) Department of Chemical and Environmental Engineering (2007). In addition, Mr. Huling was contacted to obtain the latest status on this developmental technology. The following key findings and preliminary conclusions are based primarily on EPA's presentation to CH2M HILL in 2007 and recent discussions with Mr. Huling of EPA.

- Sulfuric or hydrochloric acid can be used to adjust the pH. Iron can be added in a number of forms including ferric sulfate, ferric chloride, ferric nitrate and ferrous sulfate, however, ferric iron is preferred for GAC regeneration. This is because after the oxidation reaction is complete, the chloride can be more easily eluted from the GAC compared to sulfate or other anions.

- Regeneration appears to be diffusion limited. The VOC must desorb from the GAC inner pores and migrate to the outer pores that have Fe adsorbed. This is where the Fe, H_2O_2, and VOC meet and react. VOCs that more easily desorb have a net higher percent destruction (net regeneration) efficiency. Thus, methyl tertiary butyl ether (MTBE) would be expected to have a higher regeneration ability than TCE. While TCE reacts faster than MTBE, the reaction rate is diffusion limited.

- After the 2007 presentation to CH2M HILL, additional testing was done by EPA at higher regeneration temperatures. Regeneration temperatures in the range of 25 degrees Celsius (°C) to 55°C were tested. The test results indicated that increasing the temperature of regeneration significantly improved regeneration of MTBE-loaded GAC. The improvement in GAC regeneration was attributed to enhanced MTBE diffusion at higher temperatures. On this basis, it can be concluded that Fenton regeneration of GAC loaded with TCE would also be enhanced at higher temperature due to faster TCE diffusion.

- Mr. Huling estimated the H_2O_2 dosage at 1.0 lbs/lb GAC for each regeneration cycle, which is consistent with his estimated dosages in his other technical papers on MTBE treatment. In one paper, it was noted that 30.3 moles of H_2O_2 were used per kilogram (kg) of GAC. Since each mole of H_2O_2 is 34 grams, 30.3 moles is 1,030 grams (1.03 kg) H_2O_2 per kg of GAC. This dosage is based on regeneration of MTBE laden spent GAC. Additional studies would be needed to determine appropriate dosages for other VOCs such as TCE, PCE, and ethylene dibromide.

- The typical regeneration treatment included four H_2O_2 dosage steps, roughly 0.25 lbs of H_2O_2 per pound of GAC per step based on ambient temperature GAC regeneration. Based on discussions with Mr. Huling, the consumption of H_2O_2 would likely be reduced if regeneration were done a higher temperature.

ITEM	REMARKS
	• The regeneration of MTBE-loaded GAC was not 100% complete. Some residual MTBE was retained on the GAC. However, the overall adsorptive capacity of the GAC was not reduced. The overall regeneration efficiency ranged from 42% to >90% in the various tests that were conducted, depending upon the focus/purpose of the given regeneration test. • There was no definitive data regarding how many times spent GAC can be loaded, regenerated and subsequently reloaded. In one study, a GAC sample initially loaded with MTBE was subjected to up to 10 cycles with only a 10% overall loss of GAC capacity (1% per cycle, which is very low). However, this data did not have adsorption loading cycles in between the regeneration cycles. In this test, a GAC sample was simply treated with ten (10) sequential regenerations steps. • Some iron leakage during the GAC loading cycle was evident in some of the EPA test work. Although not discussed in the EPA studies, the use of a greensand filter to capture iron leakage may be required in a full-scale treatment system. The need for iron removal is site-specific and can be addressed during site-specific pilot testing. • In general, the Fenton process for GAC regeneration needs more development and optimization of the variation process parameters including regeneration temperature, hydrogen peroxide dosage and iron addition to the GAC as well as testing on other organics such as TCE instead of with MTBE as found in the literature sources used in this study. There are limited studies on Fenton GAC regeneration studies involving other VOCs.
5.0	**PROPOSED FENTON REAGENT GAC REGENERATION PROCESS** For purposes of developing rough order of magnitude cost estimates, a representative process scheme and basis of design were developed. The treatment process is summarized in general terms below. **Process Discussion** The design basis for the feasibility study reflects current operating conditions at the existing Chemical Spill-10 In-Plume (CS-10 IP) Building D GAC groundwater treatment plant as summarized below: • Nominal Groundwater Flow Rate = 600 gallons per minute (gpm) • Nominal TCE Concentration = 40 micrograms per liter (µg/L) • Nominal GAC usage with off-site GAC regeneration: Approximately 4 GAC replacements per year at 20,000 lbs each (adsorption cycle time of 3 months); annual GAC usage approximately 80,000 lbs/year

ITEM	REMARKS
	The CS-10 IP Building D plant was chosen for this study since it has some of the highest influent TCE concentrations and consequently uses more GAC per year than most other AFCEE/MMR treatment plants (five exchanges in 2009). In the proposed process, untreated groundwater would be fed into a two (2) GAC vessel system configured in a lead/lag/polishing configuration for TCE removal. During operation, there would be two control points; the first one for maximizing GAC usage and the second one for controlling final GAC effluent at or below nondetect TCE concentrations. The first control point is at the lead GAC effluent. When the lead GAC bed becomes fully saturated (e.g., bed influent concentration equals bed effluent concentration), the lead GAC bed is removed and is regenerated on site using the Fenton process. The previous lag bed becomes the lead bed and the freshly regenerated GAC bed becomes the lag bed. The second control point is the final effluent from the lag bed. When this final GAC effluent exceeds nondetect levels, the lag GAC bed is placed in the lead position and the previous lead GAC bed is regenerated on site using the Fenton Process. The freshly regenerated GAC bed becomes the lag bed. Based on the above description, the need to regenerate the lead GAC bed and to reconfigure the GAC beds (e.g. switching the lag bed to lead position and regenerating the lead vessel and its subsequent placement in the lag position) would be triggered by whichever control point is exceeded first. Under ideal conditions, the lead bed would become saturated (e.g., effluent equals influent concentration) first before the lag bed effluent exceeds detection levels. However, if the lag bed effluent reaches 1 µg/L before the lead bed is saturated, the GAC reconfiguration and regeneration process would be triggered, albeit premature from the perspective of maximizing TCE loading on the lead bed. In real operations, if the second control point is triggered before the first control point is triggered, more frequent onsite regeneration cycles would be required. With this approach, the loading on the lead GAC bed can be maximized. At the same time, the lag GAC bed serves as a polishing step. For Fenton process regeneration, the spent GAC would have to be initially impregnated with iron under acidic conditions. This is done by filling the spent GAC vessel with ferric chloride solution at about pH 3 to pH 3.5 and allowing the GAC to soak in the solution for several hours. Hydrochloric acid can be used in the acidification step. Hydrogen peroxide solution is then added at a total dosage of about 1 lb H_2O_2 per lb GAC. Peroxide addition is typically done in four steps, using about 0.25 lb H_2O_2 per lb GAC in each step. It should be noted that a thorough review of existing materials of construction of the GAC system (GAC vessels, vessel internals, influent/effluent piping and fittings, etc.) would have to be done to make sure the materials of construction are compatible with the acidic regeneration conditions before a Fenton based regeneration process is used. It is known that the GAC vessels

ITEM	REMARKS
	themselves are epoxy coated, which should provide corrosion resistance, but other GAC system components may not be suitable. For purposes of this study, the cost estimate includes as allowance for replacement of piping, valves and fittings in and around the GAC system. In addition, health and safety plans as well as Operations and Maintenance (O&M) plans and procedures would have to be modified to account for the presence of hot acidic solutions. Existing system pressure safety relief valves would have to be reviewed to make sure they can handle any gases (such as carbon dioxide) evolved during regeneration. Before addition of the hydrogen peroxide, the acidic ferric chloride solution would be recirculated through a new heater to increase the temperature of the GAC in the range of about 120 degrees Fahrenheit (°F) to 150°F to increase TCE diffusivity and enhance overall regeneration efficiency. The heat load is about 9,000,000 British Thermal Units (BTUs). This can be done over a 3-hour period which would require a small 3,000,000 BTU/hour rated heater. The heater can be electric or fuel fired (oil, natural gas). At the end of the regeneration process, the acidic water is drained from the GAC vessel and could be pumped into a storage tank and reused for the next regeneration after augmentation with additional acid and ferric chloride and subsequently with peroxide. The GAC vessels would be rinsed with water after being drained. The rinse water would be neutralized and recycled back to the front of the treatment process. After the lead bed has been regenerated, this GAC bed is placed into the lag position and the previous lag vessel is placed in the lead position as previously described. **Process Uncertainties** **Hydrogen Peroxide Dosage.** The hydrogen peroxide dosage was varied from a pessimistic case of 1.0 lb per lb GAC down to an optimistic case of about 0.5 lb H_2O_2 per lb GAC for cost estimating purposes. The initial dosage of 1 lb H_2O_2 per lb GAC is based on initial EPA regeneration studies at ambient temperature and without any optimization or refinement. The optimistic case of 0.5 lb H_2O_2 per lb GAC is based on the assumption that further studies and testing would reduce the hydrogen peroxide demand. **Number of Regeneration Cycles.** The effect of residual TCE on the regenerated GAC as well as the number of regeneration cycles that could be achieved before the GAC had to be replaced must be accounted for. In EPA studies, it was reported that although the residual adsorbed contaminant after regeneration was substantial, the overall adsorptive capacity of the GAC for a given contaminant did not change. Consequently, for purposes of this study, residual TCE of about 20% was assumed after Fenton process regeneration. Based on current TCE adsorption cycles of about 4 months at the CS-10 Building D facility, the adsorption cycle time based on Fenton regeneration would be about 20% less or about 3.2 months due to presence of the residual TCE.

ITEM	REMARKS
	Although the EPA studies did not determine the number of times that GAC could be regenerated using the Fenton process, it was noted that several characteristics of the GAC that are known to affect GAC adsorptive capacity such as surface area and pore volume, etc., did change over time. To account for the uncertainty in the number of Fenton regeneration cycles that could be attained, a range of cycles from 5 total up to 20 total were assumed as part of a sensitivity analysis. The range of H_2O_2 dosages and number of regeneration cycles before GAC replacement is assumed to be required is summarized in Table 1 for cost estimating purposes. **Potential Need for Third GAC Bed for TCE Polishing.** Previous MTBE pilot studies indicate the regeneration is not 100% complete and some pilot studies showed some leakage of MTBE from regenerated GAC during the subsequent adsorption loading cycles. It is possible the same phenomenon could occur with TCE in the case of the MMR facility. In this case, a three (3) bed GAC system might be required. The first two beds would rotate as lead/lag vessels as they load and get regenerated over time. The third or polishing bed (virgin or thermally reactivated GAC) would always stay in the third position until its effluent approached or exceeded nondetect levels, at which time it would be replaced. With this approach, the loading on the lead GAC bed can be maximized. At the same time, the third GAC bed serves as a polishing step and provides a further degree of assurance that the GAC system effluent will be below the nondetect TCE effluent concentration target. The potential cost associated with the need for a third GAC bed for trace TCE polishing purposes is included in a separate cost estimate as discussed below. The need for a TCE polishing bed can be studied further during pilot testing that would be needed to better develop the Fenton regeneration process. **Potential Need For Greensand Filter**. A greensand filter may be required to remove any iron leakage off the regenerated GAC. As previously noted, some of the EPA test papers indicated some iron leakage may occur. Since treated water is discharged in various ways at MMR, including by reinjection into the ground, iron removal may be needed to keep the injection wells from fouling due to iron precipitation. The greensand filter would be placed either after the last GAC vessels. The potential cost associated with the need for a greensand filter is included in a separate cost estimate as discussed below. The need for a greensand filter can be studied further during pilot testing that would be needed to better develop the Fenton regeneration process.
6.0	**COST ESTIMATES** Cost estimates were developed for two scenarios as indicated below to provide a range of potential costs: • **Cost Scenario 1**—Based on new Fenton process regeneration plus existing two-bed GAC configuration and no greensand filter.

ITEM	REMARKS

- **Cost Scenario 2**—Same as Scenario 1 but includes a new third GAC polishing bed for TCE polishing and a greensand filter.

For each of these scenarios, preliminary capital and O&M costs were developed for several Fenton regeneration process variables identified in Table 1.

The resulting costs are summarized in Table 2-1 (for Cost Scenario 1) and Table 2-2 (for Cost Scenario 2) and represent a range of costs based on optimistic to pessimistic cases for hydrogen peroxide usage and number of GAC regeneration cycles that might be achieved. The capital costs ranged from about $710,000 to about $2,080,000 for Cost Scenarios 1 and 2, respectively. The annual O&M costs ranged from as low as about $67,100 for Cost Scenario 1 to as high as $143,000 for Cost Scenario 2 compared to O&M costs of about $85,800 for current operations at the CS-10 Building D treatment plant.

It should be noted that there are no capital costs associated with current operations. The capital costs in Table 2-1 for Cost Scenario 1 are the same since these cases include the same existing 2-bed GAC system and a new Fenton regeneration process. Similarly, the capital costs in Table 2-2 for Cost Scenario 1 are the same since these cases include all Scenario 1 costs plus costs for a third GAC polishing bed and a greensand filter system. All the capital cost estimates also include an allowance for upgrading existing piping, valves, fittings, etc., around the existing GAC vessels to be compatible with acidic regeneration conditions.

It should be noted that in all the capital cost estimates, no GAC system costs were included to replace the existing two-stage GAC system in the cost estimates. It was assumed for purposes of this feasibility study that the existing epoxy lined GAC vessels at CS-10 IP Building D GAC groundwater treatment plant would be compatible with the periodic acidic Fenton regeneration process (pH 3 to pH 3.5). If the existing GAC vessels are found not be compatible with the Fenton process, then additional significant capital cost would be required to replace the existing two (2) GAC vessels with more acid resistant materials of construction.

The O&M costs for current operations reflect primarily the current cost of periodic off-site regeneration of spent GAC plus some additional minor O&M cost allowances. The projected O&M costs for the Fenton regeneration cost scenarios include costs primarily for GAC makeup (annualized costs of regenerated GAC replacement after assumed number of regeneration cycles; and annual replacement of polishing bed GAC in the case of Cost Scenario 2), chemicals and O&M labor and parts cost for incremental equipment associated with the Fenton regeneration process.

More detailed capital cost information is included Tables 3-1 and 3-2 for Cost Scenarios 1 and 2, respectively. Equipment costs and various unit costs used in developing the cost estimates are included in the cost table.

ITEM	REMARKS
7.0	**RESULTS AND CONCLUSIONS** The Fenton process for GAC regeneration is still in the developmental stage with most of the development work being done by the EPA office of Research and Development. All of this work to date has been based on MTBE adsorption on GAC and the subsequent regeneration of the GAC. The cost estimates developed for this feasibility study are preliminary Rough-Order-of Magnitude-level cost estimates due to the developmental stage of this process, the many process treatment parameters that have yet to be established for a TCE based adsorption/regeneration process and the various assumptions that were made in order to develop cost estimates. The preliminary cost estimates developed in this feasibility study show that the capital cost can range between about $710,000 to about $2,080,000 depending upon required equipment assumptions. The annual O&M costs range from about $18,700 less than current operations to as much as about $57,200 higher than current operations depending upon required equipment assumptions and assumed process treatment variables. Based on these preliminary cost estimates, the Fenton regeneration process has generally higher overall costs compared to the current operations based on off-site transport and thermal regeneration of spent GAC. Further development of the Fenton process for GAC regeneration at the pilot scale would be required to better establish treatment process parameters to determine more accurate capital and O&M cost estimates. In addition, further development of the Fenton process could improve the economics of this process. The technology is promising and at the minimum, the development of this technology should be tracked to monitor its progress and potential future applicability to MMR treatment systems. No conclusions can be made regarding potential positive sustainability impacts using the Fenton regeneration process compared to current operations due to the developmental stage of the Fenton regeneration process. Although the Fenton process has the advantage of potentially reducing the need for offsite transport and thermal regeneration of spent GAC, the Fenton process has higher chemical usage, requires energy for heating the process and may require periodic polishing GAC bed replacement. In addition, the two lead/lag beds would require periodic replacement depending upon how many times the GAC could be regenerated, which has not been determined.
8.0	**COST ESTIMATE DISCLAIMER** The Rough Order of Magnitude estimates contained in this report have been produced using one or more of the following methods: • Comparison with similar work performed by contractors, with material and labor adjustments based on observed or perceived site conditions and/or on information provided by local engineers or operators of the facilities that have been surveyed.

ITEM	REMARKS
	• Ratio methods, using known subcontractor/material/equipment level of effort costs as guides • Historical labor costs for engineering, permitting, planning, etc. based on CH2M HILL experience The purpose of these estimates is to assist in establishing priorities for decision making and to aide in evaluating the potential cost of performing the tasks identified. These estimates cannot be relied upon to establish funding levels for individual tasks, as neither preliminary nor detail design engineering has been performed in sufficient detail to provide quantities from which to estimate. Survey and as-built information has been, in general, nonexistent. Soils reports and other environmental information have not been available. In many instances, the methodology for performing the work has not been determined and this will have a great impact upon the ultimate cost of the effort. For instance, local permitting and impact to neighboring properties have not been studied. The final costs of the project and the resulting feasibility will depend on actual labor and material costs, competitive market conditions, actual site conditions, final project scope, schedule, and other variable factors. Therefore, great caution should be used in utilizing these rough order of magnitude numbers for anything other than preliminary prioritization purposes. Once the priorities have been established by the client, the traditional engineering, procurement and construction process of can be followed.

Subject: **ON-SITE GRANULAR ACTIVATED CARBON REGENERATION PILOT TEST FINAL REPORT**	Issued By: Patricia de Groot for Brad Johnson, P.E. CH2M HILL, PROJECT ENGINEER

ITEM	REMARKS
1.0	**INTRODUCTION**
1.1	**Purpose** This document presents the results from the pilot testing of techniques for on-site regeneration of liquid-phase granular activated carbon (GAC) used in treatment plants owned by the Air Force Center for Engineering and the Environment (AFCEE) associated with the Installation Restoration Program at the Massachusetts Military Reservation (MMR) for removal of chlorinated volatile organic compounds (VOCs) such as trichloroethene (TCE) and tetrachloroethene (PCE) from groundwater. The purpose of the pilot test was to determine the technical feasibility of regenerating the granular activated carbon utilizing techniques that may not require transport of spent GAC off-site, as is currently performed.
1.2	**Background** Currently, spent GAC is transported to an off-site facility for thermal reactivation. Based on high GAC change out frequency experienced at the site (47 GAC exchanges in calendar year 2010, 20,000 pounds [lbs] per exchange), regeneration of GAC on-site and/or in-vessel may provide cost savings and reduce the overall environmental impacts of the remediation program by reducing emissions associated with transportation and the thermal reactivation process. Consequently, the pilot study tested two methods of GAC regeneration to determine the impact on GAC performance. The two methods tested were regeneration by desorption with hot water followed by destruction of desorbed contaminants by an advanced oxidation process (AOP), and microwave regeneration.
1.3	**Overview** Two methods of regenerating spent GAC were evaluated. The first method relied on high temperature water flushing of GAC to remove adsorbed contaminants from the GAC, which would be followed by treatment of the desorption water with an AOP, using a combination of ultraviolet (UV) light and hydrogen peroxide in a separate reactor. Theoretically, for a full-scale process, a solution of hot water and hydrogen peroxide would be pumped through the spent GAC bed and then sent to an external AOP reactor to destroy contaminants before being recirculated back through the GAC bed. This process would be continued until the contaminants are desorbed from the GAC and destroyed in the external AOP reactor. This approach would potentially allow regeneration of the GAC in existing vessels without the need to remove the GAC for offsite regeneration.

Distribution: AFCEE: Rose Forbes, Bob Power, Admin. Record
CH2M HILL: Pat de Groot, Brad Johnson, Doc. Control

ITEM	REMARKS
	For the hot water desorption pilot test, spent GAC was generated by a pilot scale adsorption system at Chemical Spill-10 In-Plume (CS-10 IP) Building D. The spent GAC was shipped to CH2M HILL's Applied Sciences Laboratory (ASL) in Corvallis, Oregon for regeneration. Once regenerated, the GAC was returned to MMR and reinstalled into the pilot scale adsorption columns to repeat the adsorption cycle. Due to results discussed later in this report, only one cycle of adsorption and regeneration of GAC using the same GAC was done to evaluate the regeneration performance. The second method of on-site GAC regeneration evaluated was treatment of spent GAC with microwave radiation. This treatment was performed offsite by CHA Corporation, which has performed similar microwave regenerations for other clients in the past. For a full-scale process, the spent GAC would be transferred from GAC vessels into a suitably sized on-site microwave reactor to regenerate the GAC, with subsequent transfer of the regenerated material back into the GAC vessels. Note that the microwave technology cannot be employed in-vessel since the microwave regeneration process produces temperatures of nearly 1000°F and the lining in the GAC vessels is only rated for up to 150°F. The spent GAC for testing this second regeneration method was generated at the same time and in the same manner as for the AOP pilot study (in the pilot scale adsorption system at CS-10 IP Building D). The spent GAC was shipped for regeneration at CHA Corporation's laboratory facilities in McClellan, California. Once regenerated, the GAC was returned to MMR and reinstalled into the pilot scale adsorption columns to repeat the adsorption/regeneration cycle two times in the same manner as describe above for the AOP process. To evaluate the bed service life of both the hot water desorbed and microwave regenerated GAC against the bed service life of the thermally reactivated GAC currently in use at MMR (a coal-based reactivated GAC identified as custom-segregated reactivated [CSR] GAC provided by Carbon Activated Corporation), the TCE adsorption breakthrough cycle times for the regenerated GAC were compared with the cycle times for the fresh CSR GAC (the control GAC for these tests) in the test control beds after each regeneration cycle. Additionally, several analyses were performed on the regenerated and control GAC to evaluate adsorption properties. These analyses are described in detail in Section 2. Work performed in support of this evaluation included preparation of a work plan (AFCEE 2010); installation of a new adsorption pilot scale test column system at CS-10 IP Building D; installation of hot water desorption test apparatus at CH2M HILL's Applied Sciences Laboratory in Corvallis, Oregon; execution of the hot water desorption process; concurrent microwave regeneration at CHA Corporation's McClellan, California facility; and preparation of this report on the results of the testing and a summary of findings and recommendations.
2.0	**TECHNICAL APPROACH**
2.1	**Pilot Adsorption System** The GAC regeneration pilot test required representative spent GAC for regeneration testing and means to test the regenerated carbon for adsorption performance monitoring. A pilot adsorption system was constructed at the CS-10 IP Building D plant to treat actual plant influent water to produce GAC loaded with VOCs suitable for regeneration testing. The loaded GAC used in the regeneration testing was produced in the pilot system by treating influent groundwater ranging between 37-46 micrograms per liter (µg/L) TCE until the GAC effluent concentration reached 1 µg/L (the GAC exchange criteria at MMR systems). The same system was used to monitor the adsorption performance of the regenerated GAC. The pilot adsorption system is described in detail in a project note titled "GAC Regeneration Pilot Test Work Plan" 392712-EES-CS10-PRJNOT-002 on February 1, 2010 (Appendix A).

ITEM	REMARKS
	Basis of Design The pilot system was designed, constructed and operated in order to develop data to enable comparison of the performance of regenerated GAC with fresh CSR GAC after two regeneration cycles. The primary GAC performance criterion was the difference in adsorptive capacity of the GAC vs. control GAC, as indicated by differences in time required for the column effluent TCE concentrations to reach the GAC exchange criteria of 1 µg/L. The pilot columns were run at flow rates of approximately 0.45 gallons per minute (gpm) each, in order to provide a reasonable adsorption cycle time that allowed completion of at least two complete adsorption/regeneration cycles during this evaluation. Based on historical performance of the full-scale GAC system at CS-10 IP Building D, this desired adsorption cycle time was estimated to be about eight weeks. In order achieve an approximate eight week adsorption cycle time, a GAC bed depth of about 4 feet (ft) was used in the 4 inch-diameter column with a length of 10 ft. The dry mass of each GAC column bed was approximately 10 lbs. The columns were sized for a per-column flow rate of 0.45 gpm for a superficial velocity of approximately 4.5 gpm/ft^2, which is in the range of typical GAC installations. However, the corresponding empty bed contact time (EBCT) was relatively low at approximately 5.8 minutes. This is not a problem for proof of concept pilot testing because the reduced EBCT is analogous to capturing the TCE breakthrough front within a typical GAC bed at some intermediate depth, instead of waiting for it to pass through into the GAC effluent. Monitoring concentrations at mid-bed sample ports allow for tracking of the TCE as it progresses through the column. *System Description* The pilot adsorption column system process and instrumentation diagram (P&ID) is shown in Figure 1. A photograph of the system is shown in Figure 2. To reduce cost and complexity, the pilot system drew from and discharged to the full-scale CS-10 IP piping without the use of additional pumps. The inlet was drawn from a sample port at the booster pump discharge (at 60 pounds per square inch [psi]), and the outlet discharged to a sample port on the booster pump influent (at 8 psi). The pressure differential across the pilot system drove the flow through the columns. The pilot system consisted of six parallel down-flow columns, piped to allow for independent and simultaneous testing of GAC produced by two different methods of regeneration, and control GAC (two columns for each GAC to be tested). All of the columns were connected to common influent and effluent headers. The influent header contained an upstream valve for reducing flow and pressure in the system below the full-scale influent pressure. Each column was equipped with a flow control valve for individual flow rate settings. Flow rates through each column were measured through an in-line rotameter. System pressures were monitored from gauges in three locations on each column; prior to the cartridge filters, after each cartridge filter (also at the column inlet), and at each column outlet. Water samples were obtained from sample ports located pre-GAC, two GAC in-bed ports, and post-GAC. The in-bed ports allowed progression of the adsorption front to be tracked through the bed without having to wait for column breakthrough. *TCE Breakthrough Monitoring* The pilot testing for each type of regenerated carbon involved monitoring the columns for TCE breakthrough in much the same manner as done for full scale systems. Actual CS-10 IP Building D influent (at approximately 40 µg/L TCE) was distributed in parallel to the six adsorption columns until the effluent from each column reached the breakthrough point which is defined as the point when the GAC effluent is at, or greater than 1 µg/L TCE.

ITEM	REMARKS
	Sampling of the common influent to the pilot columns was done on a bi-weekly basis. Sampling to determine the location of the TCE adsorption front was done once a week at the uppermost GAC bed intermediate sampling points until the TCE concentration reached or exceeded 1 µg/L. During subsequent sampling events, the sample was then taken from the next lower sample port, again until the TCE concentration again reached or exceeded 1 µg/L. During subsequent sampling events, the sample was then taken from the effluent sample port. Each pair of columns was taken offline when the effluent concentration reached or exceeded 1 µg/L. After completion of the adsorption run, the GAC was removed from the adsorption test columns. The GAC for hot water desorption and microwave regeneration was packed in coolers and shipped for overnight delivery to the two test laboratories. Upon return of the regenerated GAC from each regeneration test, the GAC was loaded back into the same adsorption vessel from which it was removed except for the control columns, which were always loaded with fresh CSR GAC. The adsorption cycle was then repeated. Differences in TCE breakthrough times between the hot water regenerated GAC, the microwave regenerated GAC and the fresh CSR control GAC, are discussed in Section 3.
2.2	**Analytical Methods** *TCE in Water* For the pilot adsorption system at MMR, water samples were analyzed for VOCs by U.S. Environmental Protection Agency (EPA) Method 8260 at Analytics Environmental Laboratory, LLC of East Portsmouth, New Hampshire. The EPA Method 8260 was also used to measure the TCE in water for the hot water desorption and AOP testing at ASL. *TCE on GAC* <u>Sample Collection and Extraction Method</u> Before analysis could be done, representative samples of GAC had to be obtained. The method used to obtain a representative sample of GAC was based on an ASL protocol for repeatable statistically viable composite sampling of GAC for analysis (Standard Operating Procedure No. GEN70.01). This procedure involved first mixing the GAC in 5 gallon buckets using a sample splitter/recombination approach. This was performed on the initial set of three columns of GAC returned from the MMR pilot system. From that initial bulk mixing, five pounds of GAC was spread into a large pan for multi-incremental sampling. A grid was placed over the pan and samples of GAC were taken from each section for a total quantity of 60 grams to obtain a representative composite sample for analysis. There were a few modifications to this protocol for this specific application such as the GAC was not dried before taking samples. The multi-incremental sampling approach was not used when collecting samples directly from the desorption column. In those instances where sampling was done, the column GAC was mixed inside the column and multiple core samples in a cross sectional pattern were taken to obtain homogenous samples. The method for extracting TCE from the GAC to determine TCE loading was modified throughout this project. Initially, the extraction method was based on a modified EPA Method 5035, “Extraction of Volatiles from Solid Matrices”. It used a single extraction process with methanol as the solvent to remove TCE from the GAC. The methanol extraction following SW5035 was performed by adding the GAC and the methanol to a VOA vial, shaking and letting settle for 1 hour at ambient temperature. A small aliquot of this methanol is then added to a water filled VOA vial and analyzed as a water sample.

ITEM	REMARKS
	Initial jar tests conducted with this extraction method as a proof-of-concept screening prior to proceeding with pilot column testing indicated approximately 94% desorption of the TCE was achieved using 150 degrees Fahrenheit (°F) water, based on comparison of the TCE loading on the GAC before and after desorption. However, subsequent jar and column tests using this extraction method indicated desorption, but at lower levels between 40 and 65%. This variability in results suggested the extraction method needed to be improved. Additionally, initial results with this methanol extraction method did not yield data in agreement with the amount of TCE that should have been adsorbed by the GAC over the period of operation in the pilot columns. For example, assuming a flow rate of 0.45 gpm, an influent TCE concentration of 40 µg/L, 10 lbs of GAC, and 16 weeks of treatment, the results from the extraction should have been approximately 2,400 milligrams (mg) of TCE per kilogram (kg) of GAC (mg TCE/ kg GAC). However, the results from the methanol extraction method were only 2 mg/kg. These results indicate that the methanol was not effectively extracting the adsorbed TCE from the GAC. Therefore, the extraction method was modified to use carbon disulfide (CS_2) as the extraction solvent instead of methanol. After employing this preliminary CS_2 method for additional jar testing and the first round of regeneration, the CS_2 method was further modified to improve accuracy and reproducibility. The final CS_2 method was refined to include multiple extractions with the CS_2 and use of a drying agent, sodium sulfate, as discussed below. The CS_2 extraction method is based on methods Occupational Health and Safety Administration (OSHA) method 07A and National Institute for Occupational Safety and Health (NIOSH) method 1003, which are both methods for extracting volatile organic analytes from activated carbon media. The methods listed generally operate on a smaller scale of sample mass and are less intensive in the extraction process itself. The preliminary CS_2 extraction method used 30 g of the GAC with 60 mL of CS_2. In early testing phases of the preliminary CS_2 extraction method, it was determined that CS_2 contact time with GAC should be at least 4 hours. This was determined by analyzing samples with contact times ranging from as little as 10 minutes up to 24 hours. The GAC and CS_2 were added to a glass jar, sealed, shaken for 30 minutes in a sonicator bath, removed and allowed to settle for 4 hours, and finally the supernatant (solvent with TCE) was decanted for analysis. Jar tests were repeated with this preliminary CS_2 method and showed good desorption of greater than 80%. However, use of this method for the first round of column regeneration showed almost no desorption (discussed in Section 3.1). Due to the difference in the results between the jar tests and column tests, the TCE extraction method was reevaluated. It was thought that that the water may interfere with the CS_2 contacting the GAC to remove the TCE because the CS_2 is hydrophobic. Therefore, the preliminary CS_2 method was further modified to include a drying process for the GAC. This drying process involved adding sodium sulfate to the extraction solvent/GAC mixture at the beginning of the extraction. Additionally, it was thought that multiple extractions would help improve the accuracy of the method so that was included as well. The final CS_2 extraction method used 30 grams (g) of GAC and multiple, sequential extractions in CS_2. The GAC was extracted with an initial aliquot of solvent and 20 g of drying agent (sodium sulfate) to help remove water from the solvent/GAC mixture. The GAC was sonicated for 30 minutes in a sealed container, then removed and let stand for 4 hours. Once 4 hours elapsed, the solvent was decanted and 60 mL of fresh solvent was added, repeating the extraction cycle. This process was repeated three times for a total volume of 180 mL solvent. The last extraction cycle was allowed to stand for 24 hours before decanting the solvent. Multiple solvent extractions were found to be important in determining levels of TCE on GAC. In a comparison test of the multiple extraction technique used with the CS_2, the following values were determined for the sequential extraction processing of a spent or loaded GAC sample.

ITEM	REMARKS

- Initial extraction: 1,246 mg/kg
- Secondary extraction: 318 mg/kg
- Tertiary extraction: 63 mg/kg

Additively, these results represent a TCE loading on the GAC of 1,627 mg/kg (wet weight). Estimating the percent moisture in this GAC sample at 35% (similar to other GAC aliquots tested), the dry weight TCE loading would be 2,503 mg/kg, which is close to the expected value of about 2,400 mg/kg of TCE based on influent concentrations and the total flow volume sent through the GAC column. Additionally, this method was tested with and without the drying agent. There was a 15% increase in the TCE concentrations when using the drying agent so it was used in the final CS_2 method.

Results of other spent carbon sample testing using the final CS_2 method were typically in the 1,700 to 2,200 mg/kg range for TCE. Microwave regenerated carbon which showed marked decrease in TCE concentrations (see later discussion) exhibited nondetect results when using the final CS_2 method.

Analytical Method

After performing a methanol extraction on the GAC, the extraction solvent was injected into a 40 mL VOA vial and run as a water sample with EPA Method 8260 that uses gas chromatography/mass spectrometer technology (coupled with a purge and trap volatiles preparatory system). The concentrations were converted to solids units (mg/kg) using the mass of GAC and the volume of methanol used in the extraction.

For the CS_2 extracted samples, the CS_2 extraction solvent from the sequential processing steps was collected into a single vessel and a small amount was injected directly into a gas chromatograph. The gas chromatograph was outfitted with a flame ionization detector system. The concentrations were converted to solids units (mg/kg) using the solvent volume, mass of sample, and percent moisture correction of the mass.

GAC Properties

In addition to testing the adsorptive capacity of regenerated GAC by comparing breakthrough durations after regeneration, two analytical tests were conducted on the fresh CSR GAC and on the final batch of regenerated GAC for comparison of specific GAC properties: iodine number and gravimetric adsorption energy distribution (GAED).

The iodine number is a relative indicator of adsorption pore volume in an activated carbon. It does not necessarily provide a measure of the ability of the carbon to adsorb specific compounds. The GAED analysis provides data on the pore volume and adsorption energy distribution in the GAC sample. The purpose of this testing is to determine if these properties (which indicate the ability of GAC to adsorb low concentrations of contaminants), are degraded by repeated regeneration using hot water desorption or microwave regeneration methods.

The iodine number and GAED testing were done by Professional Analytical Consulting Services (PACS) Laboratories in Coraopolis, Pennsylvania.

ITEM	REMARKS
	Data Quality Because this pilot test is for internal development purposes only, the only analytical information collected was raw data that was reported on analytical summary reports (form 1s1). No formal Quality Assurance/Quality Control (QA/QC) program was implemented, although standard method QC elements were analyzed whenever possible to ensure data quality and a basic technical proofing was performed. Published methods available were followed to meet the requirements of the project. Raw data for testing is available for all analyses, and meets the laboratory requirements against its internal QA/QC program. Additionally, ASL is a Department of Defense (DoD) and National Environmental Laboratory Accreditation Program (NELAP) certified lab. No Electronic Data Deliverable (EDD) was required from the laboratory. Selected analytical data are presented in tables included in this document.
2.3	**Hot Water Desorption and Advanced Oxidation Process Regeneration** This testing was separated into the two processes of hot water desorption and AOP treatment of TCE water. The approach to AOP regeneration of GAC at full-scale would involve heating the GAC with hot recirculating water for specific duration of time to desorb the TCE from the GAC. Exposing the resultant TCE-laden water to UV light causes photolysis of the peroxide that is carried with the water, creating hydroxyl (OH) radicals that react with the TCE in the water. This reaction breaks the bonds of the TCE molecules thus destroying the TCE molecule. Initially, the work plan had these two phases combined as would be the case for full-scale implementation, but it was decided to separate these processes to control and evaluate them independently. This approach allowed testing of the processes independently to evaluate data for each process and avoided introduction of too many variables associated with an integrated system for purposes of this initial feasibility testing. *Hot Water Desorption* <u>Preliminary Jar Tests</u> The purpose of preliminary jar tests was to quickly perform a fatal flaw assessment from the outset to verify that the proposed process regenerates the GAC to any extent. Preliminary jar tests were conducted to evaluate TCE removal from the GAC at three different temperatures of hot water: 130˚F, 150˚F and 180˚F. These temperatures were selected because 150˚F is the upper temperature limit for the GAC vessels on-site at MMR based on manufacturer information. The 130˚F and 180˚F temperatures were selected to evaluate if a lower and higher temperature had any significant impact on the TCE removal from the GAC. The jar tests were conducted in 1-L glass jars. Jars were filled with 15 g of spent GAC, 500 mL of deionized water, sealed, and placed in a warm bath to reach desired temperature. Jar lids were loosened periodically during the heating process to eliminate the pressure build up. Once the desired temperature was reached, the jars were shaken every 15 minutes for 8 hours. The GAC was then analyzed for residual TCE. The GAC used for the preliminary testing was from the bulk spent GAC from an MMR vessel that had broken through at 1.7 µg/L. The bulk spent GAC was found to have very low levels of TCE on the GAC, only 2 mg/kg. Therefore, additional loading of the GAC was achieved with water spiked with TCE to be more representative of the mass loading anticipated from the pilot column testing, about 2,400 mg/kg. The GAC was combined with deionized water spiked to TCE concentration of 96.6 mg/L in a large, headspace-free vessel and mixed with a large stir bar for 24 hours. Results of the jar tests are provided in Section 3.1.

ITEM	REMARKS
	The first time the preliminary jar tests were performed, the methanol extraction method was used. When the extraction method was modified using CS_2 instead of methanol, the preliminary jar tests were repeated. Since higher temperatures would theoretically result in most effective desorption, only the 150˚F and 180˚F temperatures were tested for this run of jar tests, and GAC from the first round of the MMR pilot columns was used. No additional TCE loading of the GAC was necessary for these tests. Column Tests For this initial proof of concept testing, the hot water desorption was evaluated separately from the AOP treatment so the hot water was recirculated but not treated. The ASL constructed a pilot treatment system to cycle hot water through the GAC. A P&ID of the system is shown in Figure 3 and a photograph in Figure 4. The system consists of a single column constructed of similar size and materials as the six columns constructed for the pilot adsorption cycles at the CS-10 IP Building D facility. All materials used in contact with the hot water were either polyvinyl chloride, Teflon, or stainless steel (for the filter body and collection lines only). Water samples were obtained from sample ports in the influent and effluent to the GAC column. The system was used to regenerate the GAC, which was then sent back to MMR to repeat the adsorption/regeneration cycle. Preliminary column tests used 20 L of hot water circulated through the column. Initial tests were run with the same bulk spent carbon as used for the preliminary jar tests. The GAC was loaded with additional TCE by running water spiked with TCE through the column in the downflow direction for 12 hours. For regeneration, 20 L of 150˚F water was circulated through the column in the upflow direction at 1.0 L/min for 48 hours to test the system before loading the spent GAC from the pilot columns into the system for regeneration. Initial results indicated approximately 50% removal of TCE from spent GAC by flushing with hot water, but the analysis was performed using the methanol extraction method. The GAC from the first round of regeneration was reloaded in the pilot adsorption system at MMR and, after achieving breakthrough in the pilot adsorption system, was regenerated a second time in the hot water desorption system as described for the preliminary column tests. The TCE extraction method with methanol was used for testing the GAC during the first round of regeneration. However the results indicated such low levels of TCE on the GAC before regeneration that the regeneration was repeated with GAC from the control GAC columns, using the revised preliminary CS_2 method that used a single extraction to determine TCE loadings on the GAC before and after regeneration. These results provided more representative data for TCE on the GAC before regeneration but showed little or no removal after regeneration. The jar tests determined that the CS_2 extraction method resulted in good extraction efficiency of TCE from the GAC, however the first round of hot water regeneration did not result in effective removal of TCE from GAC. Therefore, the hot water regeneration method for the second round was modified. The thought was that the mixing of the GAC as done in the jar tests may have enhanced the TCE desorption. Therefore, the column system was modified to allow for fluidization of the GAC while circulating the hot water to mimic the mixing or shaking that was done in the jar tests. The column had to be doubled in length and the water volume doubled to 40 L. The flow rate was increased from 1 L/min to 13 L/min for the fluidization and was run for 24 hours. Additionally, a second batch of 40 L was used to determine if additional TCE would desorb in a second round with clean water which would be the case if the desorption water was treated with AOP before recirculating back to the column. The second round used the final CS_2 extraction method with a drying agent and multiple extractions.

ITEM	REMARKS
	AOP Pre-Testing Use of an AOP process to regenerate GAC is a novel process that has not been commercially developed. As such, some initial investigative pre-testing was conducted to determine if the process is fatally flawed or not, and to determine suitable test parameters/conditions for pilot testing. The work plan indicated that a brief assessment would be made for using ozone instead of UV light. However, the option of using ozone with hydrogen peroxide as an AOP process was eliminated because of transfer efficiency concerns, rapid ozone decay at the elevated desorption temperature, and concerns regarding the efficiency of the hot water desorption process. The AOP system was designed to treat the effluent water generated by the desorption process by creating a hydroxyl radical from the hydrogen peroxide and UV light which attacks and cleaves the double bond in the TCE. This process involves adding hydrogen peroxide at a specified dose, mixing with an in-line mixer, and exposing the water/peroxide solution to UV light in a closed reactor system. CH2M HILL consulted with Trojan Technologies in Ontario, Canada, when developing and pre-testing oxidizing conditions. Trojan Technologies is a major supplier of UV/peroxide AOP systems to municipalities and industry worldwide and has extensive experience with this technology. A description of the AOP regeneration pilot system that was constructed and operated at ASL is provided in this section. A P&ID of the system is shown in Figure 5. Initial testing was performed to determine the scavenging potential of the desorbed hot water from the preliminary jar tests. The 150°F and 180°F desorption water was sent to Trojan and tested for hydroxyl radical scavenging potential. From this information Trojan UV suggested initial peroxide dosages as well as a flow rate through the UV reactor. The AOP system is summarized below: • Total collected water available for processing: 18 L. • Suggested initial peroxide dosage target: Set this equivalent to TCE concentration in water collected from GAC desorption. The concentration of TCE in the water prior to AOP treatment was 0.94 mg/L. Three peroxide doses were used to assess system effectiveness: 0.47 mg/L (50% dose), 0.94 mg/L (100% dose), and 1.89 mg/L (200% dose). In addition, multiple passes of the 200% dosed water were performed to determine if any remaining TCE would be removed from additional UV treatment. • Flow rate through AOP system: 200 mL/min (200 to 300 mL/min suggested). • Internal volume of UV Reactor: 2.2 L. • Total residence time in reactor: 11 minutes. • Reactor type: Low pressure UV lamp. Originally, the expected concentration of TCE in the 18 L of desorption water was approximately 250 mg/L. This expectation was based on the TCE loading capacity of the GAC and the known volume of water in the system. However, the TCE concentration in the desorption was actually about 0.02 mg/L due to the MMR requirement to remove GAC from service when the effluent concentration reaches only 1 µg/L. This concentration of TCE is very low to conduct the AOP parameter testing. Therefore, the water was spiked with TCE to a concentration of 0.94 mg/L to use for the testing. The methodology for the testing is described below: • The 18 L of water was adjusted to the desired peroxide dose and homogenized before initiating system flow. • To start the test, the reactor was filled with clean, un-dosed water and the lamp was started and allowed to warm to operating temperature.

ITEM	REMARKS
	• After the lamp reached operating temperature (estimated at 5 minutes by Trojan UV), desorption water was pumped through the UV reactor for an initial flushing period of 10 minutes. For the next 20 minutes, the effluent was sent to a waste collection stream and saved for later use (4 L volume). After 20 minutes of operation, the pH and dissolved oxygen (DO) concentration of the effluent were recorded. The effluent was collected for 5 minutes in a brown amber bottle with Teflon lined lid (1 L volume) followed by two 40-mL samples for VOC analysis. • The peroxide dose was increased to the next desired peroxide dose and the previous step was repeated. • One effluent sample was treated for a second and third time to evaluate additional TCE reduction. • The progress of the AOP treatment process was monitored by frequent analysis for TCE and residual hydrogen peroxide concentrations in the hot recirculating solution. In addition to the samples collected for TCE analysis and residual hydrogen peroxide analysis in the recirculating solution, the pH and temperature were also monitored. Precautions were taken against loss of TCE by inadvertent air stripping or volatilization losses by operating in a sealed, headspace free environment and passing enough water through the UV reaction cell to help minimize heat added to the system. Collection of samples was performed immediately after the UV reactor and performed without any agitation or creation of bubbles due to excessive flow rates. All containers were sealed immediately after collection and placed in a walk-in cooler at 4 degrees Celsius. Vials were preserved as per EPA method 8260 prior to collection, as well.
2.4	**Microwave Regeneration** Microwave regeneration of GAC uses microwave energy to destroy adsorbed contaminants. The microwaves are absorbed by molecules with dipoles, but bypass chemically similar molecules that lack dipoles. They penetrate into many materials very deeply, transforming energy directly into heat by exciting molecules into rapid oscillatory motion. Based on these attributes, microwave energy offers several practical advantages over conventional heating methods, including reduced thermal gradients, selective heating, rapid energy deposition, and acceleration of certain chemical reactions. The ability of a material to absorb microwave energy is determined by the dielectric properties of the material and of the frequency of microwave energy applied. The GAC regeneration test unit uses microwaves at frequencies of 2,450 megahertz (MHz). This frequency is the same as that found in home microwave ovens and equipment for generating and applying this frequency of power is commonly available. This test involved sending the TCE loaded GAC to CHA Corporation in McClellan, California for the microwave treatment. The regenerated GAC was sent back to CS-10 IP to repeat the adsorption/regeneration cycle two times on the same batch of GAC. CHA Corporation has conducted similar studies on GAC for EPA and DoD and was already set up to conduct this type of testing. Therefore, development of pilot test conditions by pre-testing was not required based on CHA's experience with microwave technology. CHA used existing pilot scale equipment to test up to 10-lb batches of TCE-loaded GAC from the CS-10 IP pilot scale adsorption columns. A work plan for microwave regeneration of spent GAC including pilot test apparatus set up and testing procedures and protocol was prepared by CHA corporation and was subsequently reviewed and approved by CH2M HILL. The first round of microwave GAC regeneration pilot testing was done during the week starting 02 August 2010. The planned work included a site visit by a CH2M HILL process engineer to the CHA laboratory facilities in McClellan, California, to confirm that the pilot test apparatus and test procedures were consistent with the approved work plan and to witness the first regeneration test (Appendix B).

ITEM	REMARKS
	A P&ID of the system is shown in Figure 6. The pilot test apparatus consists of two reactors. The first reactor (the regeneration reactor) is used to regenerate the GAC with microwave energy to vaporize and/or destroy the VOC vapors. The saturated GAC is loaded into a 3-inch quartz tube in this 3-kilowatt (kW) microwave reactor. The reactor is preheated and then run. Nitrogen is used as sweep gas to remove TCE and water vapors generated from regenerating spent carbon. The nitrogen off-gas flows from the regeneration reactor through a heat exchanger to remove any remaining moisture before going the second reactor (the oxidation reactor) where TCE vapors are oxidized. The oxidation reactor is another 3-kW reactor packed with a mixture of granular silicon carbide and oxidation catalyst. Measurements of total hydrocarbon are recorded for inlet and outlet of the oxidation reactor. When the inlet concentration is below 50 parts per million (ppm), the microwave generators are stopped. It has been found in previous tests by CHA Corporation that when the hydrocarbon concentration of the outlet sweep gas reaches approximately 50 ppm the regeneration of carbon in the microwave reactor is complete. The nitrogen gas flow continues to cool the GAC until the outlet gas temperature is about 100˚F. This process is repeated until all of the GAC is regenerated. A detailed description of the methodology is presented in the CHA results report (see Appendix C). For the first round, approximately 40 lbs of wet GAC (approximately 20 lbs GAC on a dry basis) was sent to CHA for testing on 14 July 2010 and arrived at CHA Corporation on 15 July 2010. The GAC was regenerated in approximately 4- to 4.5-lb portions. A total of nine regeneration runs were conducted to treat the entire 40-lb sample. Microwave regenerated GAC was shipped back on 10 August 2010 and arrived at MMR on 17 August 2010. The regenerated GAC was placed back into the pilot adsorption system for a second adsorption cycle run starting on 18 August 2010. Samples of the microwave regenerated GAC from each column batch (approximately 60 grams) were sent to ASL for analysis of residual TCE content and iodine number. For the second round, the same GAC as regenerated previously, was sent to CHA Corporation on 27 December 2010 and received on 28 December 2010. The same procedure and apparatus were used as for the first round. The GAC from each test column was kept separated when shipped and regenerated. A total of six regeneration runs were conducted on one batch and a total of four regeneration runs were conducted on the other batch. The number of regeneration runs is dependent on the weight of the batch sample. In this case, one batch was 21.14 lbs and the other was 15.17 lbs. The regenerated GAC was shipped back on 24 January 2011 and arrived at MMR on 31 January 2011. It was put back into service in the pilot system at MMR on 22 February 2011.
3.0	**RESULTS AND DISCUSSION**
3.1	**Hot Water Desorption** *Preliminary Jar Desorption Tests* Initial preliminary hot water jar desorption tests were performed on a sample of spent GAC from active vessels at MMR (not from the pilot columns). This testing was done to determine proof of concept and to establish the degree of TCE desorption in relation to temperature. As with most proof-of-concept studies, test protocol and procedures often need to be adjusted as the test work proceeds and experience is gained with the test system. In these test studies adjustments were made in procedures to minimize VOC losses to small vapor spaces in the test equipment as well as changes in analytical procedures to better estimate the TCE on the GAC before and after regeneration which is used to evaluate the effectiveness of the regeneration processes. Therefore, the

ITEM	REMARKS
	In the column desorption test, the same volume of water was recirculated through the bed for the full course of the process. Buildup of contaminant in the wash water may have inhibited further desorption of contaminant from the GAC. This is not representative of how the process would work at full-scale since the hypothetical full-scale system would include on-line AOP-based destruction of contaminants in the recirculating wash water, thereby delivering relatively contaminant-free wash water to the GAC bed at all times. These column test results indicated that TCE is not being effectively desorbed from the GAC by the hot water desorption process as tested. Due to previous jar tests results that indicated better desorption of TCE with the hot water, additional jar testing with the final CS_2 method were performed to re-evaluate the jar hot water desorption process. These additional jar test results were similar to the results seen in the column test for the second round of regeneration, thus indicating poor desorption with hot water based on the hot water desorption processes tested to date. The discrepancy between previous jar test results and the additional jar test results is likely due to modifications of the analytical method used to measure TCE on the GAC. The final CS_2 method of extraction developed is a multi-step process requiring a 24-hour contact time, and has been shown to be effective at recovering the adsorbed TCE from spent GAC for analysis. Previous extraction methods used either methanol or CS_2 as the extraction solvents with a single extraction. For these reasons, the conclusion was reached that the early jar test results with the methanol method and the preliminary CS_2 method were not accurately measuring the TCE on the GAC before and after desorption.
3.2	**Advanced Oxidation with UV** A preliminary set of tests were performed using the AOP unit to help establish an approximate hydrogen peroxide dose and flow rate through the UV cell to destroy TCE in the desorption water. *UV AOP Tests* UV AOP testing was performed on water from the column desorption test using spent GAC from the pilot test columns (Round 1). There were two columns of GAC regenerated which provided two separate batches of desorption water for testing. This test was performed on August 9, 2010. Table 3 contains the results from this test. The TCE concentration of the water treated was 0.94 mg/L after spiking the water with TCE to a level that would show decreases with the various dosing scenarios. A total of six different peroxide doses were tested. The peroxide doses were equal to 0.5, 1, and 2 times the TCE concentration. The TCE reduction for these doses was 91.4, 95.4, and 98.2%, respectively. The second pass of the effluent from the 2X dose, resulted in 99.8% destruction of the remaining TCE from 17 to 1.5 µg/L. However, there was only a very slight further reduction for the third pass with the effluent from the second pass, 1.5 to 0.6 µg/L. The lowest residual peroxide remaining in the treated water was 71.3% indicating lower doses of peroxide could probably be used to avoid overdosing if there is a concern of the peroxide impacting the GAC for a full-scale scenario. The pH and DO was only slightly impacted. The pH increased slightly and the DO decreased slightly with the addition of the peroxide (Table 3). The results from the AOP process were promising with reduction of TCE by greater than two orders of magnitude. The reaction proceeded as expected (lowered the pH and DO), and the values were within reasonable expectations. The second round of desorption data indicated little or no TCE was removed from the GAC so no AOP testing was conducted on the desorption water.

ITEM	REMARKS
3.3	**Microwave** The results from the microwave carbon regeneration are presented in Table 4. The first batch of GAC sent to CHA Corporation for regeneration had a TCE concentration of 1,200 mg/kg. After regeneration, the GAC had a concentration of 67.4 mg/kg, indicating approximately 94% desorption. The method used for determining the TCE on the GAC was with the preliminary CS_2 method with only one round of extraction. The results of the microwave regeneration for second round were similar to those from the first round. The second batch of GAC sent to CHA Corporation for regeneration had a TCE concentration of 2,407 mg/kg. After regeneration, the GAC had a concentration of 6.0 mg/kg, indicating greater than 99% desorption. The method used for determining the TCE on the GAC was with the final CS_2 method with multiple rounds of extraction. A report from CHA Corporation is included as Appendix C. The report provides the starting mass, regenerated mass, liquid recovered and percent weight lost for each regeneration cycle. The report states that it is not possible to directly correlate the energy use from the laboratory tests for a full scale system, because such small quantities of GAC were used. However, an estimated energy use of 29.5 kW for 100 lbs of wet GAC per hour is provided based on some assumptions. Given the amount of moisture that was in the GAC, CHA recommends that for full-scale implementation a drying step be added before the microwave process.
3.4	**Iodine Number and GAED Analyses** The results from iodine number testing are presented in Table 5 and in Appendix D. Samples of fresh (unused) CSR GAC, spent CSR GAC, and regenerated GAC (from Round #1 and #2) were sent to PACS Laboratory for iodine number testing. The fresh unused CSR GAC had the highest iodine number of 920 and the spent CSR GAC had an iodine number of 734, or 80% of the fresh CSR GAC. The hot water regenerated GAC and microwave regenerated GAC had similar iodine numbers of 835 and 837, respectively, which were about 91% of the fresh CSR GAC. After the second round of microwave regeneration, the iodine number was slightly higher at 856 which is 93% of the fresh CSR GAC. An iodine number analysis was not done for the second round of hot water regenerated GAC because other data indicated the hot water desorption was not effective. The results from the GAED analysis are provided in Table 6 and in Appendix E. In addition to results from the samples sent from this pilot testing, PACS also provided data for a typical coal based GAC used as a control. These data are provided in the table for comparison purposes. For five of the six types of typical GAC application, the fresh CSR GAC had slightly higher GAED values suggesting greater adsorption capacity compared to the typical GAC. The second round microwave regenerated GAC had values less than the fresh CSR GAC suggesting reduced absorption capacity compared to the fresh CSR GAC. However, the microwave regenerated GAC had higher values than the typical coal-based GAC for three of the six types of applications; Types IV to VI (including Type V which is probably most relevant for the MMR application). The GAED analysis was not done for the second round of hot water regenerated GAC because other data indicated the hot water desorption was not effective.

ITEM	REMARKS
3.5	**Breakthrough Monitoring** The results from the breakthrough monitoring are presented in Table 7. Breakthrough is defined as the time when the TCE concentration at a sample location was equal or greater than 1 µg/L. The initial round to load the GAC with TCE had varied durations to breakthrough for the individual columns. Given that the same batch of fresh CSR GAC was used, same influent was used, and same quantity of GAC was used in each column, this indicated a possible issue with the flow to each column. The flowmeters for each column were tested and were found to have buildup of deposits on the shaft of the float for the meter, causing inaccurate flow readings. After this flowmeter issue was discovered, the flowmeters were run up to full scale and then down to zero daily to prevent the floats from becoming stuck in place by the buildup of deposits on the shaft. A timed bucket test was also done periodically to confirm the calibration of the flowmeters. The duration to reach breakthrough for the control GAC, the fresh CSR GAC, ranged from 91 days or 13 weeks to 126 days or 18 weeks for the initial round. After the first round of regeneration, the hot water desorption regenerated GAC reached breakthrough after only four weeks of operation. The control CSR GAC reached breakthrough at 13 weeks and the microwave regenerated carbon reached breakthrough at 17 weeks, indicating better performance than the fresh CSR GAC. After the second round of regeneration, the hot water regenerated GAC was not put back into service because analytical data showed no or little removal of TCE. The microwave regenerated carbon was put back into service along with a fresh load of CSR GAC as a control. On 11 May 2011 the TCE concentration at the effluent of the control CSR GAC column exceeded the exchange criteria of 1 µg/L, after 78 days (11 weeks) of operation. As of 18 May 2011, the TCE concentration in the lower mid-bed sample port of the microwave desorbed GAC was 0.49 µg/L. This indicates that the microwave desorbed GAC has a longer bed life than the CSR GAC, as occurred after the first round of regeneration.
4.0	**CONCLUSIONS AND RECOMMENDATIONS** The microwave regeneration data indicate that this process successfully regenerated the GAC to have equal or better performance compared to the CSR GAC used at MMR. Testing of the GAC after the first round of regeneration indicated a time to breakthrough for the CSR GAC (control GAC sample) of 13 weeks. The microwave regenerated GAC had a breakthrough time of 17 weeks after the first round of regeneration. The iodine number for the microwave regenerated GAC even after the second round of treatment was 91% of the fresh CSR GAC, indicating that the GAC retained high porosity even after multiple regeneration cycles. Additionally, the GAED data suggests that after the two rounds of microwave regeneration, the GAC still had 89 to 93% of the adsorption pore volume of the fresh CSR and higher adsorption pore volume than the typical coal-based GAC for Type 5 trace loading applications. Therefore, this technique could potentially be implemented at MMR. An issue to consider about use of the process at MMR is the wet GAC would have to be removed from the vessels to the regeneration unit and then moved back to the vessels after regeneration. A custom microwave reactor of suitable size would have to be built to handle large quantities of GAC. Although the microwave regeneration process appears to effectively regenerate GAC loaded with TCE, investigation of the financial feasibility and sustainability of full-scale implementation of the process would require substantial effort, in part because, no designs for equipment capable of treating the quantities of spent GAC generated that would be needed by the MMR systems currently exist; in order to further investigate the financial and sustainability impacts of process scale-up, such designs would need to be produced before the analysis could be completed. Another consideration is that it is likely that custom-designed equipment would require fairly high capital investment, resulting in an extended simple

ITEM	REMARKS
	payback period. Additional labor and costs associated with operation and maintenance of this type of system would also have to be considered. It is also not known if the technology could effectively regenerate GAC loaded with ethylene dibromide (EDB). In order to determine the simple payback period of full-scale implementation of the technology, further pilot testing should be considered to determine if the process can be used to regenerate GAC from EDB treatment systems. For these reasons, it is recommended that further investigation into the financial feasibility and sustainability of full-scale implementation of the microwave regeneration process be undertaken in a future task order only if funds and time are available and work efforts first focus on the other GAC treatment options (i.e., permanganate pre-treatment and use of alternative GAC products). The current hot water desorption pilot process appears to be inadequate for determining technical feasibility for full-scale regeneration. The data indicate very little removal of TCE from the GAC for each batch of hot water in a jar test or circulated through a column. Based on this information and general isotherm trends for TCE at high temperatures, it is hypothesized that the amount of TCE desorbed with each hot water pass is very small and that clean water would be needed for any significant desorption to occur. Note that a mass balance approach based on the mass of TCE desorbed from the GAC and the mass of TCE in the water after regeneration could not be used for determining the amount of TCE removed due to concerns about VOC losses from the high temperature and sampling and handling approaches to test the water and GAC. Although methods initially used to determine the loading of TCE on spent and regenerated GAC did not provide accurate results, the final CS_2 method with multiple extractions and a drying agent appears to be adequate for measuring TCE on the GAC. ASL estimates the accuracy to be approximately ± 25% with this method. Therefore, data obtained with this method is considered reliable and this method could be used for any future work. Improvements to the extraction efficiency will also continue to be evaluated during any future work. In order to further develop the hot water GAC desorption process, CH2M HILL suggests running a continuous column test that would better mimic the full-scale concept. However, instead of using an AOP for continuous destruction of TCE, we propose air stripping the TCE from the hot water before it is recirculated through the column. Air stripping would provide a straightforward way to remove the TCE from the water being recirculated without the need to manage the AOP (which would require careful control of hydrogen peroxide concentrations depending on TCE concentrations). The water would be recirculated and treated for a period of time. The GAC would then be analyzed after the set period of time to determine how much TCE was desorbed. If the results of this follow-on work result in effective desorption of TCE from the spent GAC, then the GAC would be returned to MMR for bed life testing in the pilot column system. This work was proposed to AFCEE in a draft project note titled *On-Site Granular Activated Carbon Regeneration Pilot Test Status Update*, 392712-EES-CS10-PRJNOT-003 (Appendix F), on 18 March 2011. If the results of this follow-on work result in effective desorption of TCE from the spent GAC, then the GAC would be returned to MMR for bed-life testing in the pilot column system, followed by an evaluation of the economic and sustainability impacts of implementing the technology at full-scale. This work would be done under a future task order. The AOP data indicate that this process can successfully destroy the TCE in hot desorption water with a reduction of TCE concentrations of greater than two orders of magnitude. In general, TCE destruction efficiencies in the 98 to >99% range were readily achievable. Based on results of future hot water desorption testing, additional AOP testing could be done to better define the necessary parameters for the TCE concentrations expected in the desorption water. Future AOP testing could also evaluate potential byproducts and intermediate compounds that may remain on the regenerated GAC which could

ITEM	REMARKS
	impact performance of GAC when put back into service, or result in discharge of these compounds to the environment. Also, evaluation of any byproducts or intermediates in the residual AOP treated water would help address how the residual water would need to be managed such as by being returned to the plant influent for treatment or discharged with the system effluent.

ITEM	REMARKS
1.0	**INTRODUCTION AND APPROACH** ***A. Purpose*** This document presents the work plan for the pilot testing of techniques for regeneration of liquid-phase granular activated carbon (GAC) used in the treatment plants associated with the AFCEE Installation Restoration Program at the Massachusetts Military Reservation. The purpose of these tests is to determine the feasibility or proof of concept of regenerating the granular activated carbon utilizing techniques that may not require transport of spent GAC off-site, as is currently required. The proposed tests will use pilot-scale GAC adsorption columns at the CS-10 IP Building D plant to treat actual plant influent water to produce GAC loaded with VOCs suitable for regeneration testing. ***B. Background*** Based on high GAC change out frequency experienced at the site (42 GAC exchanges in 2009, 20,000 lbs per exchange), regeneration of GAC onsite/in-vessel may provide cost savings. Consequently, this pilot test plan proposes pilot testing two methods of GAC regeneration to determine the impact on GAC performance. The two methods to be tested are microwave regeneration and advanced oxidation process (AOP) regeneration.
2.0	**GAC REGENERATION PILOT TESTING OVERVIEW** CH2M HILL will evaluate two methods that may be used to regenerate spent GAC on site at the pilot scale. In the first method, we will evaluate a method developed by CH2M HILL that relies on high temperature flushing of GAC with AOP (using combinations of ultraviolet [UV] light and hydrogen peroxide) in a side reactor. In a full-scale process, hot solution injected with hydrogen peroxide would be pumped through the GAC bed and sent to an external AOP reactor to destroy TCE before being recirculated back through the GAC bed. This process would be continued until the TCE is desorbed from the GAC and TCE destroyed in the external reactor. This approach, if feasible, would allow regeneration of the GAC in existing vessels without the need to remove the GAC for offsite regeneration.

ITEM	REMARKS
	For purposes of pilot testing, spent GAC will be generated by a pilot scale adsorption system at CS-10 IP Building D. The spent GAC will be shipped for pilot testing the AOP regeneration process at CH2M HILL's pilot test facility in Corvallis, OR. Once regenerated, the GAC will be returned to CS-10 IP and reinstalled into the pilot scale adsorption columns to repeat the adsorption cycle. Two cycles of adsorption and regeneration of GAC using the same GAC will be done to help determine if the adsorptive capacity and overall performance of the GAC will be retained after multiple adsorption/regeneration cycles. The intent of the pilot test is to determine the technical feasibility or proof of concept of this regeneration process. In the second method, CH2M HILL will have a method to regenerate spent GAC by treatment with microwave radiation tested offsite by CHA Corporation, which has performed similar microwave regeneration tests. In this process, wet GAC would be treated with microwave energy to determine if it would adequately regenerate the GAC. In a full-scale process, the wet GAC would be transferred from GAC vessels into a suitably sized microwave reactor to regenerate the GAC with subsequent transfer of the regenerated material back into the GAC vessels. For purposes of pilot testing, spent GAC will be generated in the same time and in the same manner as for the AOP pilot study described above. The loaded GAC will be shipped for pilot testing at CHA Corporation's laboratory facilities in Laramie, WY. Once regenerated, the GAC will be returned to CS-10 IP and reinstalled into the pilot scale adsorption columns to repeat the adsorption/regeneration cycle two times in the same manner as describe above for the AOP process. The intent of the pilot test is to determine the technical feasibility or proof of concept of this regeneration process. Testing will require fabrication of a pilot GAC adsorption system at CS-10 IP Building D that will be used to prepare spent GAC samples partially loaded with TCE for subsequent regeneration pilot testing in offsite facilities. The CS-10 IP pilot adsorption system will consist of six columns for preparation of multiple GAC samples and will be operated on-site with actual system influent water. The proposed pilot-scale test will be configured as six parallel 4-inch diameter, 10-foot long GAC columns as described in more detail below. Enough GAC will be procured for 3 full recharges of all six columns. The GAC currently in use at the site will be used for this pilot test. This GAC is provided by Carbon Activated Corporation and is a coal-based reactivated GAC identified as custom-segregated reactivated (CSR) GAC. Labor for operation and on-site sampling of the pilot adsorption columns will be provided by O&M staff under a separate task order. During the test, all six columns will be run to the GAC breakthrough point defined as 1 µg/L TCE in each GAC column effluent. It is anticipated that this will take approximately 8 weeks to occur. Upon reaching TCE breakthrough, the spent GAC from four of the columns will be removed for regeneration utilizing the AOP and microwave regeneration processes, two columns from each regeneration process. Regeneration testing will be performed on both GAC samples from each adsorption cycle for purposes of test result reproducibility. The remaining two columns will serve as Control Columns or control samples for comparing performance with subsequently regenerated GAC as described below. AOP Regeneration will be performed at CH2M HILL's Corvallis, OR office/lab facility. The regeneration test will be done on GAC from each adsorption column for purposes of test redundancy and repeatability. After regeneration, the GAC will be returned to MMR and re-installed in the columns. The two control columns will be refilled with fresh CSR GAC as a control and the adsorption cycle will be repeated. This adsorption-regeneration cycle of parallel operation of regenerated GAC vs. two columns of fresh CSR GAC will be repeated two times.

ITEM	REMARKS
	Microwave regeneration pilot testing will be performed at CHA Corporation's Laramie, WY laboratories. After regeneration, the GAC will be returned to MMR and re-installed in the columns. The regeneration test will be done on adsorbed GAC from each adsorption column for purposes of test redundancy and repeatability. This adsorption-regeneration cycle of parallel operation of regenerated GAC vs. two columns of fresh CSR GAC will also be repeated two times concurrently with AOP regeneration testing. TCE adsorption breakthrough cycle times for the AOP regenerated GAC and the microwave regenerated GAC will be compared with the cycle times for the fresh CSR GAC in the test control beds after each regeneration cycle. This comparison will be used to determine the degree to which the regenerated GAC adsorption capacity is reduced, if any, after 3 regeneration cycles using AOP or microwave processes. Work to be performed includes preparation of a work plan; installation of a new adsorption test column system at CS-10 IP Building D; installation of AOP regeneration test apparatus at CH2M HILL's Corvallis, OR laboratory; execution of the AOP testing; concurrent microwave testing at CHA Corporation's Laramie, WY laboratories; and preparation of a report on the results of the testing and a summary of findings and recommendations.
3.0	**TEST METHODS** This section describes the test methods that will be used for pilot regeneration testing. ***A. Advanced Oxidation Process (AOP) Regeneration*** This approach to regenerating the GAC involves heating GAC with hot water recirculating water at a temperature of 150°F to desorb the trichloroethylene (TCE) from the GAC. The 150°F will be used because, per the vessel manufacturer's specifications, this is the upper limit of temperature that can be used in epoxy-coated carbon steel vessels like those at CS-10 IP. While recirculating, the hot water is dosed with hydrogen peroxide (H_2O_2) and exposed to UV light at a wavelength of 254 nm. The UV light causes photolysis of the H_2O_2 creating hydroxyl (OH) radicals that react with the TCE in the water. This reaction breaks the bonds of the TCE molecules thus destroying the TCE molecule, but often creates oxidation by-products such as chloromethane, 1,1-DCE, vinyl chloride, which in turn, could be further oxidized. The laboratory will design and construct a pilot treatment system which can cycle hot water through the GAC, dose with H_2O_2 and expose to UV light and continue this process until the influent and effluent TCE concentrations of the GAC column are equal which should indicate that no more TCE is being removed. The residual hydrogen peroxide concentration in the GAC column effluent will be monitored and adjustments to hydrogen peroxide dosing will be made to keep residual hydrogen peroxide concentrations at target levels (to be determined during AOP pre-testing as discussed below). The test system is shown in Figure 2. The testing will be done on both GAC samples. The regenerated GAC will be shipped back to CS-10 IP to repeat the adsorption/regeneration cycle two times using the same GAC each time. The planned work includes a 2-day trip by a CH2M HILL process engineer working on this project to visit the pilot test laboratory in Corvallis, OR to assist the lab technicians with pilot equipment setup and to witness the first regeneration test The planned testing would be completed in about 39 weeks as discussed in Section 7 below. <u>AOP Regeneration Pre-testing</u> Use of an AOP process for regeneration of GAC is a novel process that has not been commercially developed. As such, some initial investigative pre-testing is needed to determine if the process is

ITEM	REMARKS
	fatally flawed or not, and to determine suitable test parameters/conditions for pilot testing such as hydrogen peroxide dosage and UV light exposure if the process is potentially viable. CH2M HILL will consult with Trojan Technologies in Ontario, Canada when developing and pre-testing oxidizing conditions. Trojan Technologies is a major supplier of UV/H2O2 AOP systems to municipalities and industry worldwide and has extensive experience with this technology. Pre-testing will be conducted in two main phases: 1) Technology Screening Pre-testing and 2) Process Parameter Pre-testing. In addition, a brief assessment of the potential suitability of using ozone instead of UV light in the AOP regeneration process will be done. Technology Screening Pre-testing. In the first phase, a grab sample of spent GAC that has been saved from the most recent GAC change out from the existing full-size GAC CS-10 IP system will be pre-tested as soon as possible. The purpose of this technology pre-screening test is to quickly perform a fatal flaw assessment from the outset to see if the proposed regeneration process regenerates the GAC to any extent even before the initial pilot scale GAC adsorption cycle is even completed. If AOP regeneration pre-screening testing shows some positive results, then the pilot testing will continue. If no GAC desorption is detected, CH2M HILL will discuss the preliminary screening pre-testing results with the client in order to make a decision on whether or not to proceed with the rest of the pilot study. The technology screening pre-test will be performed while the initial pilot GAC adsorption cycle is underway and before it is completed. Is should be pointed out that the spent GAC from the existing full-size GAC system to be used for technology screening pre-testing may not truly representative of the spent carbon that would be generated from the pilot scale adsorption system. This is because the pilot scale system will generate a small amount (about 10 lbs) of GAC that has been loaded to the point that the TCE in the effluent is about 1 ug/L. In contrast, the spent GAC used for technology screening pre-testing will be a grab sample from a very large amount of existing spent GAC in which the grab test sample may be from the top of the column with relatively high levels of adsorbed TCE or the grab sample may be from the bottom of the column with relatively low levels of adsorbed TCE. This is because there is no easy and practical way to get a representative sample from a 20,000 lb lot of spent GAC. However, despite this potential difference in GAC loading characteristics, the technology screening pre-testing should provide some indication of whether or not the AOP regeneration process will work or not, and will provide a basis for stopping the pilot study program at this point or to continuing with the pilot test. The technology screening pre-testing will be performed using the same basic methodology as discussed below for process parameter pre-testing. Process Parameter Pre-testing. Process parameter pre-testing will be done on actual spent GAC from the initial pilot scale adsorption cycle. This pre-testing phase will build upon the previous technology screening pre-testing results by developing process parameters/conditions to be used during the AOP regeneration pilot testing. This is in contrast to the initial technology screening pre-test that will be focused simply on proving the concept based on a testing a potentially non-representative grab sample of GAC from the existing full scale GAC system and not on finding more suitable pilot test operating conditions for conducting the actual pilot study. The pre-test will provide preliminary confirmation that the planned 150° F regeneration temperature is adequate. The regeneration temperature confirmation testing will be based on monitoring the TCE concentrations in the hot recirculating hydrogen peroxide solution during pre-testing. If the hot solution circulating through the GAC increases in TCE concentration as it flows through the bed, this indicates that TCE is being desorbed off the GAC and that some level of GAC regeneration may be

ITEM	REMARKS

occurring. If pre-testing indicates that regeneration is not occurring at 150°F, then pre-testing at higher temperatures up to 210°F will be done (see optional higher temperature AOP testing discussion below). If pre-testing indicates that a higher regeneration temperature in the range of 150 to 210°F is required, CH2M HILL will notify AFCEE project staff to get approval to proceed with higher temperature regeneration testing for subsequent pilot testing.

Ozone Based AOP Assessment. Although UV light has been assumed for AOP regeneration treatment, ozone has also been used successfully in AOP processes along with H_2O_2. UV light has been selected over ozone for pilot testing because of concerns about ozone degradation at the planned testing temperature of 150°F. However, during the AOP pre-testing phase discussed above, the use of ozone for AOP treatment will be briefly investigated to confirm that it is not appropriate for this application.

Optional Additional Adsorption/Regeneration Cycle

The basic pilot test plan is limited to two adsorption/regeneration cycles so that the basic pilot test can be completed by October 31, 2010. However, we recommend that at least 3 cycles be completed to better assess the impact of repeated GAC regenerations on adsorption cycle times and performance. This optional testing would simply repeat the prior two cycles one more time. This would add about 11 additional weeks to the overall project schedule. The cost for the proposed additional test cycle is included in the cost estimate as a separate line item for consideration.

Optional Higher Temperature AOP testing

The proposed AOP pilot testing as described above is limited to 150°F maximum for compatibility with the existing GAC vessels at CS-10 IP. However, consideration should be given to testing the AOP process at even high temperatures to determine if better or more complete regeneration can be achieved. Although higher temperature in-situ regeneration would not be compatible with the existing CS-10 IP GAC vessels, higher temperature regeneration could be potentially applicable at future AFCEE or DOD sites where more temperature resistant GAC vessels could be specified during procurement.

Accordingly, a final optional adsorption/regeneration test is proposed to be conducted at about 210°F. This is close to the boiling temperature of water and would allow regeneration in atmospheric, non-pressurized vessels. This higher temperature test can be easily done with the planned pilot scale regeneration equipment in CH2M HILL's laboratory. Ideally, even higher temperatures could be tested, however, then the system would have to be pressured to say 25 psig to test at about 250°F. CH2M HILL's pilot scale equipment is not set up for pressurized testing and a special custom designed, pressurized pilot scale test system would have to be constructed requiring more time and cost.

The cost for the proposed higher temperature regeneration testing at 210°F is included in the cost estimate as a separate line item for consideration.

Optional Regeneration Testing of Fully Saturated GAC

A final adsorption cycle in which the GAC is loaded to saturation (e.g. effluent TCE conc. equals influent conc.) followed by AOP regeneration is proposed for consideration. This test would reflect a common lead/lag configuration that is often practiced to maximize GAC usage in which the first bed is allowed to reach full saturation. If we find that AOP regeneration proves to be successful on our lightly loaded GAC (with a 1 µg/L TCE concentration in the GAC effluent), then it makes sense to do at least one test to see if fully saturated GAC can be regenerated as well. If this also proves to be

ITEM	REMARKS
	successful, then AFCEE would have the possibility of developing a regeneration process that could be used at many of their GAC based groundwater treatment facilities with this common lead/lag configuration, both at current and future facilities. This optional test could be done concurrently with the optional higher temperature AOP regeneration test at 210°F. ***B. Microwave Regeneration*** Microwave regeneration of GAC uses microwave energy. The microwaves are absorbed by molecules with dipoles, but bypass chemically similar molecules that lack dipoles. They penetrate into many materials very deeply, transforming energy directly into heat by exciting molecules into rapid oscillatory motion. Based on these attributes, microwave energy offers several practical advantages over conventional heating methods, including reduced thermal gradients, selective heating, rapid energy deposition, and acceleration of certain chemical reactions. The ability of a material to absorb microwave energy is determined by the dielectric properties of the material and of the frequency of microwave energy applied. The GAC regeneration test unit uses microwaves at frequencies of 2450 MHZ. This frequency is the same as that found in home microwave ovens and equipment for generating and applying this frequency of power is commonly available. This test will involve sending the TCE loaded GAC to CHA Corporation in Laramie, WY for the microwave treatment. The regenerated GAC will be sent back to CS-10 IP to repeat the adsorption/regeneration cycle two times on the same GAC. . CHA Corporation has conducted similar studies on GAC for EPA/DOD and is already set up to conduct this type of testing. Microwave testing of GAC regeneration has been previously conducted at CHA Corporation test facilities for other projects and development of pilot test conditions by pre-testing is not required based on CHA's experience with microwave technology. The planned work includes a 2-day visit by a CH2M HILL process engineer to CHA's laboratory facilities in Laramie, WY to review the regeneration equipment set up and to witness the first regeneration test.
4.0	**PILOT ADSORPTION TESTING DESCRIPTION** The GAC regeneration pilot test requires the preparation of spent GAC material that has been partially loaded with TCE and which can be subsequently used for regeneration at offsite facilities. The pilot testing also requires the repeated adsorption. The following describes the preparation of spent loaded GAC needed for regeneration testing. **A. GAC Adsorption and TCE Breakthrough Monitoring** The pilot testing will involve monitoring the columns for TCE breakthrough in much the same manner as would be done at full scale. Actual CS-10 IP Building D groundwater will be fed in parallel to six (6) adsorption columns (see Figure 1 and adsorption column set up discussion below) until the effluent from each column reaches the breakthrough point which is defined as the point when the GAC effluent is at, or greater than 1 µg/L TCE. Sampling will be done approximately once a week at the first GAC bed intermediate sampling point for about the first 4 weeks. Sampling will then be changed to the second intermediate sampling point and will continue for about another 4 weeks based on the assumption that TCE breakthrough would occur at the first intermediate sample point at the end of the first 4 week period. This approach will allow tracking of the TCE breakthrough front as it progresses through the GAC bed. The effluent from the bottom of the GAC bed would also be sampled weekly for about the last 4 weeks with the intention of stopping the adsorption cycle when the final effluent reaches about 1 µg/L TCE concentration. The sampling durations noted above are only approximations and actual adsorption cycle times may be shorter or longer than the estimated 8 week adsorption cycle time.

ITEM	REMARKS

After reaching the GAC breakthrough point, the GAC will be allowed to drain from the adsorption test columns. The GAC for AOP and microwave regeneration testing will be packed in coolers and shipped for overnight delivery to the two test laboratories.

Upon return of the regenerated GAC from each regeneration test, the GAC will be loaded back into the same adsorption vessel from which it was removed except for the control columns, which will always be loaded with fresh CSR GAC. A GAC sample labeling method will be developed to make sure the regenerated GAC is always returned to its original adsorption column. The adsorption cycle will then be repeated. Differences in TCE breakthrough times will be compared between the AOP regenerated GAC, the microwave regenerated GAC and the fresh CSR control bed GAC. Differences in adsorption cycle times, if any, will provide a direct indication of differences in adsorptive capacity.

Description

A description of the adsorption pilot system to be constructed and operated at CS-10 IP Building D is provided in this section. The proposed adsorption column layout is shown in attached Figure 1. Although the basic concepts discussed below will be incorporated, the actual layout may change during fabrication.

- To reduce cost and complexity, the pilot system will draw from and discharge to the full-scale CS-10 IP piping without the use of additional pumps. The inlet will draw from a sample port at the booster pump discharge (60 psi), and the outlet will discharge to a sample port either on the booster pump influent (8 psi) or after the full-scale lead vessel (40 psi). The pressure differential across the pilot system will drive the flow through the columns.

  On the surface, some concern may arise from the fact that the pilot effluent may be discharged into the CS-10 IP feed line *upstream* from where the pilot system takes its feed. However, because pilot flow rate will be less than 1% of full-scale system flow, the pilot effluent will be greatly diluted in the full-scale CS-10 IP piping before it reaches the pilot influent point. In the event unforeseen complications arise from recirculating even small amounts of flow through the pilot system, it will be designed to discharge alternately to the outlet line of the full-scale primary vessel. Alternately, the pilot columns could discharge to the building sump, but this is the least desirable option because a sump pump failure would lead to a floor flood and plant shutdown.

- Because the pilot system will discharge upstream from at least one full-scale CS-10 IP GAC vessel, pilot column breakthrough is of no environmental concern.

- The pilot system will consist of 6 parallel down-flow columns, piped to allow for independent and simultaneous testing of 2 different methods of GAC regeneration. All of the columns will be connected to common influent and effluent headers. The influent header will contain an upstream valve for reducing flow and pressure in the system below the full-scale influent pressure.

- Each column will be equipped with a flow control valve for individual flow rate settings. Flow rates through each column will be measured through an in-line rotameter, with a nearby sample valve for calibrating and verifying flow rate.

- System pressures will be monitored from gauges in three locations on each column; prior to the cartridge filters, after each cartridge filter (also at the column inlet), and at each column outlet.

- Water samples can be obtained from sample ports located pre-GAC, two GAC in-bed ports, and post-GAC. The in-bed ports will allow progression of the adsorption front to be tracked through

ITEM	REMARKS

the bed without having to wait for column breakthrough.

Pilot Flow Rates

The pilot columns will be run at a flow rate of about 0.5 gpm each in order to provide a reasonable adsorption cycle time that will allow completion of a least two complete adsorption/regeneration cycles during the performance period of this task order. This desired adsorption cycle time is estimated to be about 8 weeks as discussed below in Section 7 regarding project schedule. In order achieve an approximate 8 week adsorption cycle time, a GAC bed depth of about 4 feet must be used. This bed depth is less than what is used in the existing GAC system at CS-10P, however, use of this shorter test bed depth will provide the shorter adsorption cycle time desired for this pilot test.

The columns will be scaled so that at a per-column flow rate of 0.5 gpm, the superficial velocity will be about 5 gpm/ft^2 which is in the range of typical GAC installations. However, the corresponding EBCT will be relatively low at less than about 6 gpm / ft^2. This is not a problem for proof of concept pilot testing because the reduced EBCT is analogous to capturing the TCE breakthrough wavefront inside a typical GAC bed at some intermediate depth, instead of waiting for it to pass through into the GAC effluent.

Scale

The pilot columns will be 4 inches in diameter, with a column length of 10 ft. The depth of the GAC beds in the columns will be 48 inches. The dry mass of each column's GAC bed will be approximately 10 pounds. To accommodate these flow rates with minimal back-pressure, common header piping will be 1-in, and individual column piping will be ½ to ¾ -in.

Materials of Construction

- Columns will be constructed of clear PVC, to enable visual observations of the condition of the media. The ends will have cam-lok fittings for easy removal, cleaning, and GAC change out.
- The column end screens will contain stainless steel screen fittings, appropriately sized to prevent the passage of GAC particles.
- Valves and piping will be constructed of Schedule 80 PVC.

Variables to Be Tested

The pilot system will be designed, constructed and operated in order to develop data to enable comparison of the performance of regenerated GAC with fresh CSR GAC after two regeneration cycles (adsorptive capacity as indicated by differences in adsorption cycle times).

B. GAC Properties Testing

In addition to testing the adsorptive capacity of regenerated GAC by comparing adsorption cycle times after repeated regenerations, two tests will also be conducted on the fresh CSR GAC and on the final batch of regenerated GAC to allow comparison of specific GAC properties: 1) the Iodine number test and 2) the gravimetric adsorption energy distribution (GAED) analysis. The iodine number test is a measurement of the surface area available for small molecules. The GAED method provides the number, distribution and type of number of adsorption binding sites and the strength of binding. The purpose of this testing is to determine if these three GAC properties, which greatly affect GAC adsorption performance, are degraded by repeated regeneration using AOP or microwave methods.

ITEM	REMARKS
5.0	**REGENERATION PILOT SYSTEM DESCRIPTION** **A. AOP Regeneration Pilot System** Description A description of the AOP regeneration pilot system to be constructed and operated at CH2M HILL laboratory in Corvallis, OR is provided in this section. The proposed regeneration scheme is shown in attached Figure 2. Although the basic concepts discussed below will be incorporated, the actual layout may change during fabrication. ▪ A single column to contain the adsorbed GAC will be constructed of similar size and materials as the six columns to be constructed for the pilot adsorption cycles at the CS-10 IP Building D facility. ▪ A regeneration system comprised of a small UV light reactor cell, heater, and a system for dosing hydrogen peroxide. CH2M HILL has conducted numerous AOP treatment studies on water and wastewater projects and will assemble a suitably scaled system for this pilot test. ▪ Water samples can be obtained from sample ports in the influent and effluent to the GAC column. Pilot Flow Rates Pilot regeneration system recirculation flow rates will be determined during the pre-testing phase. The flow rate will be flow paced in relation to the UV-absorbance of the column effluent and intensity of the UV light in the flow cells to achieve the desired dose. Variables to Be Tested ▪ The pilot system will be designed, constructed and operated in order to develop data to enable comparison of the performance (adsorptive capacity) of regenerated GAC with fresh CSR GAC after two regeneration cycles. **B. Microwave Regeneration Pilot System** CHA Corporation has conducted numerous pilot scale tests of the GAC microwave regeneration process. CHA will use their existing pilot scale equipment to test up to 10 pound batches of TCE loaded GAC from the CS-10 IP pilot scale adsorption columns. CHA uses a 25 to 50 lb per hour GAC regeneration capacity microwave test unit equipped with a 6-kW microwave generator for testing purposes in their lab.
6.0	**SAMPLING PLAN SUMMARY** This pilot study will compare the performance of two methods of GAC regeneration to fresh CSR GAC over two cycles of regeneration (three service periods). **A. AOP Regeneration Pre-Testing Approach** 1) *Ozone Based AOP Assessment (Ozone Solubility and Decay)* A test will be conducted to measure the solubility and decay of ozone in potable water at 150°F. This information will be used to confirm our preliminary understanding that UV light will be preferred over ozone in a relatively high temperature regeneration process.

ITEM	REMARKS

2) Technology Screening Pre-Testing

Testing will be conducted to determine if GAC desorption will occur to any appreciable extent as part of an initial fatal flaw assessment of the AOP regeneration technology. The screening pre-testing conditions will be relatively aggressive in terms of hydrogen peroxide dosages and UV light exposure. These testing conditions will be developed in close consultation with Trojan Technologies, Inc. The intent of the screening test is simply to demonstrate that desorption will or will not occur without too much concern for treatment process optimization during this initial pre-testing task.

3) Process Parameter Pre-Testing (TCE Desorption and Hydrogen Peroxide Dosing)

Testing will be conducted before the formal regeneration testing is started to determine the expected concentration of TCE desorption from the GAC with the 150°F hot water flush and to determine the appropriate dose of H_2O_2 needed for the regeneration testing. Spent GAC from the control columns will be used for these tests. Assuming an influent of 40 µg/L of TCE at a flow rate of 0.45 gpm for 60 days, the mass loading on the GAC will be approximately 5,900 mg. Assuming 5 gallons of potable water will be used for the hot flush and AOP treatment, the maximum TCE concentration in the water would be approximately 310 mg/L. This screening test will determine how much of the TCE can be desorbed at 150°F and identify the necessary H_2O_2 dose to treat the TCE. This test will also provide information about the impact of H_2O_2 on the GAC during regeneration. There is some concern that use of hydrogen peroxide for regeneration may degrade the GAC.

B. Adsorption/Regeneration Test Approach

1) *First Service Period*

All 6 columns will be filled with fresh CSR GAC. Samples of this GAC will be taken for iodine number and GAED analysis before the first service period begins. The columns will all be set up to run in parallel with a flow rate of 0.5 gpm per column to replicate the residence time in the full-scale system. The system will run until the GAC effluent is greater than 1 µg/L TCE. Each column will be monitored separately for breakthrough. When the column reaches breakthrough, it will be removed from operation by closing the valve and the flow rates will be adjusted accordingly to maintain a flow rate of 0.5 gpm to the remaining columns. All columns should reach breakthrough at about the same time (within a week of each other). At that time, the loaded GAC from the two AOP columns and the two control columns will be sent to CH2M HILL HILL's laboratory for AOP screening tests and then AOP regeneration. The loaded GAC from the two microwave columns will be removed and sent to the vendor (CHA) for microwave regeneration.

2) *Second Service Period*

The two control columns will be filled with fresh reactivated GAC. The AOP and microwave columns will be filled with regenerated GAC accordingly. The columns will all be set up to run in parallel with a flow rate of 0.5 gpm per column to replicate the residence time in the full-scale system. The system will run until the GAC effluent is greater than 1 µg/L TCE. Each column will be monitored separately for breakthrough. When the column reaches breakthrough, it will be removed from operation by closing the valve and the flow rates will be adjusted accordingly to maintain a flow rate of 0.5 gpm to the remaining columns. The GAC from the control columns will be removed and disposed with the other spent GAC onsite for the full-scale system. GAC

ITEM	REMARKS

from the AOP and microwave columns will be removed and shipped to the two regeneration test laboratories, accordingly.

3) *Third Service Period (Partial)*

The third service period is stopped at the completion of the third adsorption cycle with no further regenerations to complete the basic pilot study. Unless optional additional testing is done (see discussion below) samples from the AOP and microwave regenerated GACs will be taken for iodine number and GAED analysis

4) *Optional Testing*

Additional 3rd regeneration test and subsequent adsorption cycle. This optional test and would continue with the regeneration of the GAC from the previous third service period. The regenerated GAC would again be tested using both AOP and microwave regeneration methods and be subsequently placed back into the pilot adsorption columns at CS-10 IP for another regeneration cycle in order to compare adsorption cycle times with fresh CSR GAC as well as with prior adsorption cycles.

Higher AOP Regeneration Temperature Test. GAC from one AOP adsorption column from the previous adsorption cycle would be sent to CH2M HILL's regeneration test lab or regeneration a temperature of about 210°F. This would be followed by shipment of this GAC back to CS-10 IP, GAC installation into its respective column, and conducting a final adsorption cycle. This high temperature regeneration option may also be implemented earlier if results from the AOP regeneration pre-testing phase indicate that regeneration is not occurring at the planned 150°F test temperature.

GAC Regeneration on Fully Saturated GAC. One of the AOP adsorption columns form the fourth service period would be allowed to become fully saturated with TCE in which the column effluent is the same as the column influent. It is anticipated that this may take 2 or 3 times as long as previous adsorption cycles. Once the GAC is saturated, it would be regenerated at CH2M HILL's lab and then subjected to a final adsorption cycle back in the CS-10 IP pilot columns for comparison of its adsorption cycle with previous cycle times.

C. Sampling Plan

1) Breakthrough Monitoring

Sampling requirements including sampling frequency and analytical test turn-around-times (TATs) are summarized in Table 1. The sampling plan is based on the assumption that the adsorption breakthrough period is about 8 weeks. If the breakthrough period is longer, additional sampling will be required at additional cost. Influent sampling will only be done once at the beginning of the adsorption cycle and a second time at the end of the adsorption cycle based on the assumption that influent concentrations are steady and do not vary significantly over time. Sampling will be done at least weekly for two midpoint samples and effluent for each of the six columns. Samples will need to be analyzed for TCE concentrations using EPA Method 8260.

2) AOP Pre-Testing

Sampling requirements are summarized in Table 2 for AOP pre-testing. It is assumed that two screening tests may be needed to determine appropriate H_2O_2 dosing. In addition to the samples collected for TCE analysis, the pH, residual hydrogen peroxide, and temperature will also be monitored.

ITEM	REMARKS
	3) AOP Regeneration Testing Sampling requirements are summarized in Table 3 for regeneration testing. The progress of the regeneration process will be monitored by frequent analysis of TCE and residual hydrogen peroxide concentrations in the hot recirculating solution. In addition to the samples collected for TCE analysis and residual hydrogen peroxide analysis in the recirculating solution, the pH and temperature will also be monitored. Precautions will be taken against loss of TCE by inadvertent air stripping or volatilization losses. Regeneration testing is repeated a second time using GAC from the second shipped GAC sample for purposes of pilot test result repeatability and testing redundancy. *4) Analytical Deliverables* Because this pilot test is for internal development purposes only, the only analytical information collected will be raw data and basic laboratory reports. No formal QA/QC program will be implemented, although additional samples will be analyzed and a basic technical proofing will be performed. No Electronic Data Deliverable (EDD) will be required from the laboratory.

ITEM	REMARKS
7.0	**SCHEDULE** AOP treatment system development can begin within 1 week of receiving approval. After approval from AFCEE, CH2M HILL will order the materials for the AOP regeneration system. Estimated fabrication time is 3 weeks. Within approximately 39 weeks or about 9 months of starting, CH2M HILL should have completed all work and submitted a project note summarizing the results for the basic pilot test study based on the table below. This schedule should allow completion of the basic pilot testing study by October 31, 2010. As previously discussed, the work plan includes a technology screening pre-testing phase in which a grab sample of spent GAC (from a recent GAC change out event at the existing CS-10 IP facility) would be tested as soon as possible as part of a fatal flaw assessment to see if the proposed regeneration process regenerates the GAC to any extent even before the initial pilot scale GAC adsorption cycle is even completed. The results of this technology screening step would be discussed with the client to determine if the pilot test should or should not continue beyond this point. If the technology screening provides positive results, the pilot program would continue and the following discussion regarding schedule would be applicable. The project schedule is based on the assumption that the adsorption cycle time to reach TCE breakthrough will last approximately 8 weeks. However, an additional week has been included to allow time for shipment of GAC to and from the offsite regeneration test laboratories for total of 9 weeks for each adsorption cycle as shown below. In addition, the actual AOP regeneration testing for each cycle will take up to 2 weeks to treat both GAC samples, one after the other. The actual project schedule will vary depending upon the adsorption cycle times that are realized. The basic schedule only allows for 2 complete AOP regeneration cycles within the overall 39 week schedule. This will allow for completion of the test and authoring of the final report by the end of the task order period of performance; 31 October 2010. It is recommended that at least 3 complete adsorption/regeneration cycles be included. The addition of an optional third cycle would add about 11 weeks to the overall schedule for a total of about 50 weeks. This would require an extension of the task order period of performance. The addition of an optional high temperature AOP regeneration test would add an additional 11 weeks as shown below on two spent GAC samples as in previous tests. The addition of a separate regeneration test on GAC that has been fully saturated with TCE and subsequently regenerated and processed through a final adsorption cycle to test changes in adsorption cycle time would add an additional 19 weeks. This is based on the assumption that one of the adsorption columns used after the optional high temperature regeneration test is allowed to stay on the adsorption cycle until it becomes fully saturated with TCE. For purposes of the optional test schedule, it is assumed that full saturation would occur if the adsorption cycle is extended an additional 9 weeks. The actual time need to reach full saturation may differ from this assumption. The estimated 19 week schedule extension for testing fully saturated GAC could be reduced by about 9 weeks if only 1 GAC sample were tested at the optional higher regeneration temperature and allowing the second GAC sample to remain in the adsorption cycle until fully saturated for subsequent regeneration testing. This approach would save time, but the disadvantage would be that only 1 GAC sample would be available for high temperature regeneration and saturated GAC regeneration testing, respectively, instead of having two samples for each test as would have been done in all previous tests for repeatability and reproducibility purposes. The overall schedule will be affected by the actual absorption cycles (breakthrough times) that are realized; specifically whether or not the adsorption cycle times are more or less than the assumed 8 week periods. The schedule is based on the AOP regeneration testing cycles instead of the microwave regeneration cycle times because the former test method controls the schedule. Microwave regeneration testing is relatively fast compared to the planned AOP testing.

Process Parameter Pre-Testing			
TCE Concentration	310 ppm	310 ppm	Based on mass loading assuming 0.45 gpm at 40 ppb for 60 days with full desorbtion into 5 gallons of hot flush water. Note solubility of TCE is 1000 mg/L for 20C water.
Hydrogen Peroxide Dose	X ppm	Y ppm	Assume we **may** need to test two doses of H2O2 to find appropriate dose and regen temperature
VOC Samples Collected	24	24	Collect VOC samples from the influent and effluent ports every 15 minutes for 3 hrs (4 samples/hr x 2 beds x 3 hrs = 24 samples). Only 1/2 of samples, spread over pre-test period, will be analyzed; assume other samples will not be analyzed for cost estimating purposes, but will be available for analysis if necessary at extra cost.
pH Monitoring	--	--	Every 15 minutes for 2 to 3 hours
Residual Hydrogen Peroxide Monitoring*	--	--	Collect VOC samples from the influent and effluent ports every 15 minutes for 3 hrs (4 samples/hr x 2 beds x 3 hrs = 24 samples).
Temperature Monitoring	--	--	Every 15 minutes for 2 to 3 hours
TOTAL # VOC of Samples Analyzed	24		
Cost at $125/sample	$3,000		Fast 1 day TAT needed using Method 8260
Safety Factor of 2x	$3,000		Add 100% safety factor in lab costs if other parameters need to be tested (e.g. Rx time, UV power, higher regeneration temperature, etc.)
Analytical Cost Subtotal	$6,000		
AOP Technology Screening Pre-testing	1.5		Appy 1.5X factor to account for initial Technology Screening Pre-testing
Analytical Cost Total	$9,000		

* Residual hydrogen peroxide monitoring will be done using a colorimetric spectraphotometer method

TABLE 3
AOP Regeneration Test Sampling Matrix

	AOP Regen Column #3	AOP Regen Column #4	Assumptions/Notes
1st Regenerated Carbon Cycle			
TCE Concentration	TBD	TBD	Will be determined from Screening Test
Hydrogen Peroxide Dose	TBD	TBD	Will be determined from Screening Test
VOC Samples Collected	9	9	Collect VOC samples from the influent and effluent ports every 20 minutes for up to 3 hours hrs (Assumes 9 sampling times)
pH Monitoring	--	--	Every 20 minutes for up to 3 hours or as indicated from pre-testing
Residual Hydrogen Peroxide Monitoring*	--	--	Every 20 minutes for up to 3 hours or as indicated from pre-testing

MMR LGAC Regeneration Pilot Test Study
Microwave Regeneration Pilot Test at CHA Corporation, Site Visit Trip Report

MMR LGAC Regeneration Pilot Test Study-- Microwave Regeneration Pilot Test at CHA Corporation, Site Visit Trip Report

PREPARED FOR: Brad Johnson/CH2M HILL

PREPARED BY: Grigorieff, Mike/SCO

DATE: August 5, 2010

Background

A site visit was conducted by Mike Grigorieff/CH2M HILL at the CHA Corporation (CHA) microwave pilot test facility on August 5, 2010 in accordance with the project scope of work. The purpose of the site visit was to see that pilot test setup and test execution were in accordance with the approved test plan (see Attachment 1).

The site visit and tour was hosted by the owner of CHA Corporation, Dr. Chang Yul Cha. The facility is located at:

CHA Corporation
5301 Price Avenue
McClellan, CA 95652

Site Visit Notes

The site visit notes are presented below in four sections below: 1) pilot test equipment setup, 2) description of pilot test process and operation, 3) site visit observations & notes, and 4) conclusions.

Pilot Test Equipment Setup

The equipment was set up in accordance with the system described in the attached Work Plan (see Attachment #1). The major components of the system are summarized below:

- Microwave Reactor #1 (RX #1)—for heating of spent GAC and volatilization of VOCs.
- Microwave Reactor #2 (RX #2)—for destruction of desorbed VOCs
- Power Supplies for each microwave reactor
- Total Hydrocarbon Analyzer—for monitoring extent of regeneration
- Other miscellaneous equipment components are discussed in the attached Work Plan.

COPYRIGHT 2011 BY CH2M HILL, INC. • COMPANY CONFIDENTIAL

The following photo shows the key pilot test system components:

The following photo shows the system hooked up and configured for pilot testing:

Description of Pilot Test Process and Operation

Spent GAC is loaded into the microwave regeneration reactor (Reactor #1) in 4 to 4.5 lbs batches. Reactor #1 is used to regenerate the spent GAC by first driving off water and then volatilizing VOCs. A small flow of nitrogen gas is used to sweep VOCs and water vapor generated when regenerating the spent carbon out of the reactor. The nitrogen sweep gas containing TCE and water vapor is sent through a water cooled condenser to remove water vapor from the sweep gas. Air (for oxidation purposes) is introduced into the cooled sweep gas which is then sent to the microwave oxidation reactor (Reactor #2) for destruction of the TCE. The microwave reactor is filled with a mixture of granular silicon carbide (SiC) and oxidation catalyst that will destroy the TCE when the air/TCE mixture is heated to a relatively low initial catalytic oxidation temperature of about 300°F to 500°F. At this temperature, the catalytic oxidation reaction starts and the heat of reaction raises the internal media bed temperature to about 1000°F. The total hydrocarbon concentration in both the condenser and oxidation effluent are measured using a THC analyzer. The regeneration is continued until the TCE vapor concentration in the influent to oxidation Reactor #2 drops to about 50 ppmv. Based on CHA's experience, this influent concentration indicates that the spent GAC has been adequately regenerated in Reactor #1.

A schematic of the regeneration process is presented below:

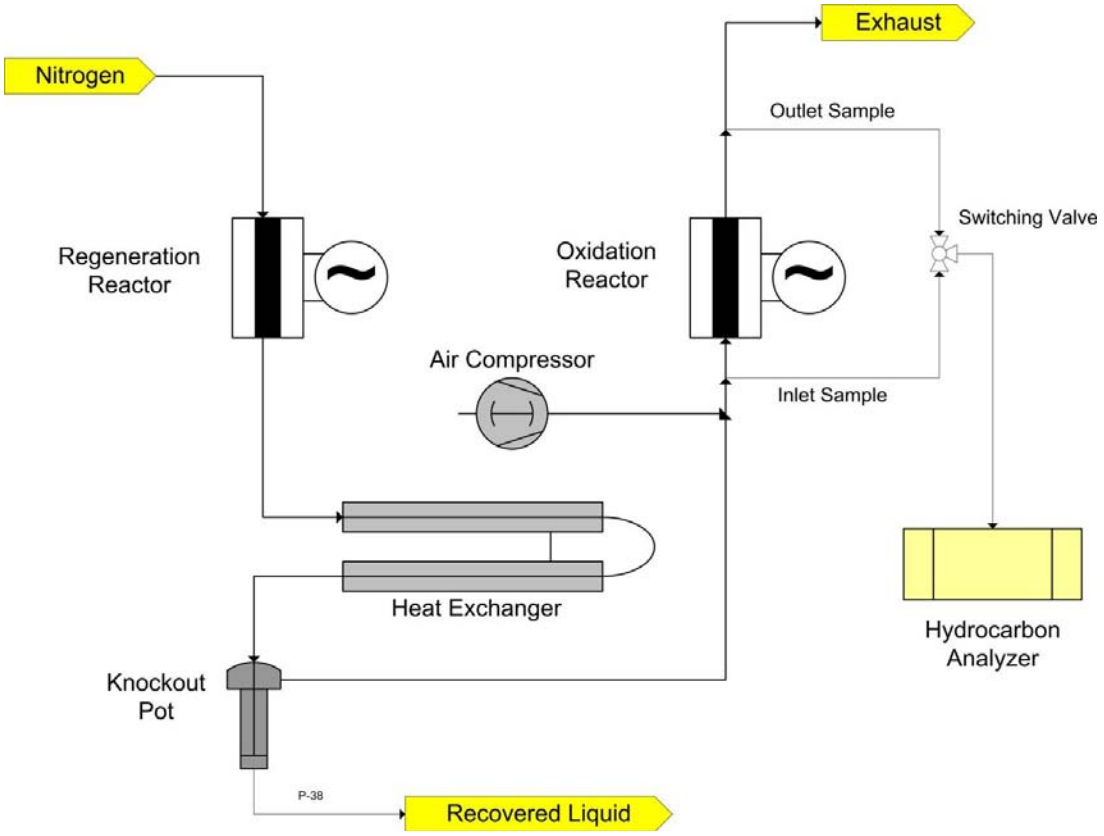

Figure 1—Pilot Test System Process Flow Schematic

COPYRIGHT 2011 BY CH2M HILL, INC. • COMPANY CONFIDENTIAL

Site Visit Observations and Notes

1. Dr. Cha reported he received 40 lbs of wet spent GAC. The moisture content was about 46% by weight.

2. Wet spent GAC was loaded manually into Reactor #1 in about 4 to 4 ½ lb batches for microwave regeneration. It takes approximately 1 hour to regenerate each batch and they could regenerate about 2 to 3 batches per day. On this basis, Dr. Cha estimated it would take them about 3 to 4 days to regenerate all 40 lbs of spent GAC.

3. The surface temperature of the regeneration reactor (Reactor #1) was in the 300°F to 460°F range The surface temperature of Reactor #1 varied from about 400°F to 460°F near the top of the reactor where nitrogen sweep gas was introduced to about 300°F to 360°F near the bottom of the reactor where the nitrogen sweep gas left the reactor. According to Dr. Cha, the internal GAC bed temperature in the regeneration reactor gets as high as about 1000°F.

4. The TCE concentration in the influent to Reactor #2 initially increases to about 300 to 400 ppmv and then drops to less than about 50 ppmv over the course of about 1 hour as measured by the THC analyzer. This reflects the fact that relatively more TCE is being driven off the spent GAC initially, and then less as TCE content on the GAC decreases over time. The regeneration process is stopped when the TCE concentration in the influent to Reactor #2 drops to about 50 ppmv. Based on CHA's experience with their microwave regeneration process, this low concentration indicates the spent GAC has been adequately regenerated.

Conclusions

The pilot test set-up and operation of the CHA's microwave LGAC regeneration pilot test system was in general accordance with the approved work plan and appeared to be performing as expected. The effectiveness of the regeneration process would be determined once the regenerated GAC is placed back into service at the MMR pilot adsorption columns and adsorption cycle times are compared with fresh GAC.

1.0 INTRODUCTION

CH2MHILL is currently operating a pilot-scale granular activated carbon (GAC) adsorption system at the Massachusetts Military Reservation (MMR) project site in order to generate spent GAC for pilot regeneration testing. The adsorption pilot test system consists of GAC columns (containing about 10 lbs of GAC each-dry basis) to treat an influent stream containing approximately 44 µg/L of TCE. The parallel pilot adsorption columns will be operated until the effluent concentration of TCE reaches 1 µg/L. Once the adsorption cycle is complete, spent GAC samples will be removed from two columns and shipped to the CHA Corporation Laboratory located in McClellan, California, for pilot microwave regeneration.

The first batch of spent GAC will consist of two separate 10 lbs (dry basis) samples of wet, spent GAC that must be tested separately. After microwave regeneration testing is completed, these samples will be shipped back to CH2MHILL MMR project site. The regenerated GAC samples will be re-loaded by CH2MHILL into their respective adsorption columns to repeat the adsorption cycle. After the second adsorption cycle is completed, the spent carbon will be sent back to CHA Corporation laboratory to repeat the microwave regeneration testing.

Prior to shipping the two 10 lb GAC samples back to the MMR project site, CHA Corporation will send approximately 60 grams of regenerated GAC from **each** 10 lb batch and after each subsequent regeneration cycle to CH2M HILL'S Applied Sciences Laboratory (ASL) so that they can be analyzed for the Iodine Number and the amount of residual TCE on the spent GAC. As requested by CHA Corporation, CH2MHILL will provide CHA the Iodine numbers and adsorption times for the TCE concentration of the adsorber outlet to reach 1 µg/L to measure the effectiveness of microwave regeneration of LGAC.

CHA Corporation has two microwave carbon regeneration units; 50-lb/hr pilot unit and 100-lb/hr mobile unit. It takes about 30 minutes for these microwave systems to reach a steady state operation. Consequently, 10 lbs of GAC sample is not sufficient amount for these microwave regeneration systems to be used for the microwave regeneration testing. The 100-lb/hr mobile unit has the microwave oxidizer that consists of two microwave reactors. This microwave oxidizer unit can be disconnected from the mobile microwave trailer and modified for testing the 10-lb samples as a fixed bed reactor. The first microwave reactor will be used to regenerate spent carbon and the second microwave reactor will be used to oxidize TCE vapor desorbed from spent carbon. Dr. C.Y. Cha discussed this possibility with Mr. Mike Grigorieff and obtained his agreement using these two microwave fixed beds for regeneration testing.

The main objective of microwave regeneration testing of LGAC is to evaluate the feasibility of regeneration of spent GAC using a microwave-based regeneration process at the MMR project site. The first step for this feasibility evaluation is to demonstrate that the microwave regeneration will restore the GAC adsorption capacity. Also, it is our goal to demonstrate that the microwave oxidation of VOCs generated from the regeneration will be oxidized at low temperature completely, resulting in no air emission during regeneration operation. We will assist CH2MHILL to see if it can be demonstrated that the microwave-based regeneration of spent GAC at one of the MMR project sites is more economical than off-site thermal regeneration currently being used.

2.0 SYSTEM FOR MICROWAVE REGENERATION PILOT TESTING

Figure 1 shows the microwave oxidizer unit that is currently connected to the 100-lb/hr mobile microwave unit. This microwave unit will be disconnected from the mobile unit for microwave regeneration pilot testing. Gas piping of this microwave oxidizer unit will be changed to pass the gas flowing out from the first microwave reactor (Reactor 1) into the vapor condensing system that will be fabricated. The gas coming out the vapor condenser flows into the second microwave reactor (Reactor 2). Each of these two microwave reactors is equipped with its own 3-kW variable power microwave generator as shown in Figure 1. Magnetron is installed inside the box shown next to the tuner. Power supplies are located inside the electric cabinet. A total hydrocarbon (THC) analyzer is also located inside the electric cabinet.

Figure 1: Picture of Microwave Oxidizer Unit

Reactor 1 will be used to regenerate spent carbon. The saturated GAC is loaded into a 3-inch quartz tube in this microwave reactor. Nitrogen will be used as sweep gas to remove TCE and water vapors generated from regenerating spent carbon. It is not necessary to use 100% pure nitrogen for sweep gas. A membrane-based nitrogen generator may be utilized to generate nitrogen for sweep gas for a full-scale carbon regeneration system. Nitrogen sweep gas containing TCE and water vapors will flows into the water-cooled condenser.

Reactor 2 will be packed with the mixture of granular silicon carbide (SiC) and oxidation catalyst. Nitrogen sweep gas flowing out the condenser will be introduced into the

COPYRIGHT 2011 BY CH2M HILL, INC. • COMPANY CONFIDENTIAL

microwave oxidizer (Reactor 2). Air will be introduced into Reactor 2 to oxidize TCE vapor remaining in the sweep gas after the condenser.
Total hydrocarbon concentration (THC) of the condenser outlet gas and Reactor 2 outlet gas will be measured by THC Analyzer that will be calibrated with methane standard gas. The THC analyzer can measure THC concentration in gas in the range of 1-100,000 ppm. The condensed liquid collected in the knockout pot will be measured at the end of testing.
The chiller currently connected to the 6-kW microwave generator in the Technikon's microwave test unit will be disconnected from this microwave reactor system and used for supplying cooling water to two 3-kW microwave generators and the vapor condenser.

3.0 MICROWAVE REGENERATION TESTING PROCEDURE

Two spent GAC samples sent by CH2MHILL will be stored in the refrigerator until the microwave regeneration testing facility is ready. Below is the step by step procedure for microwave regeneration testing for each 10-lb sample (on dry basis) of spent liquid phase GAC.

1. Unpacked the first spent GAC sample package
2. Measure the weight of spent GAC.
3. Measure the moisture content of the GAC by drying about 100 g samples at 100 °C overnight.
4. Check Reactor 2 to make sure that the quartz tube contains the mixture of 50% SiC and 50% Pt-based oxidation catalyst
5. Open the top of the quartz tube of Reactor 1
6. Fill the quartz tube with spent GAC close to the top
7. Measure remaining spent GAC to estimate the weight of spent GAC loaded in Reactor 1
8. Close the top of quartz tube
9. Start nitrogen sweep gas flow and set its rate at 1.5-scfm
10. Check for the gas leakage around Reactor 1 and Reactor 2 using soap bubble-water.
11. Start chiller and microwave cooling water pump
12. After the nitrogen flow is stabilized, start Reactor 2 microwave generator and set the microwave power at about 2.7-kW or 90% of the power level
13. Tune the microwave generator to minimize the reflected power using the tuner.
14. Start air flow to Reactor 2 and set its flow rate at 0.5-scfm
15. Preheat Reactor 2 for 30 minutes
16. After 30 minutes, start Reactor 1 microwave generator and set the microwave power at 90%

COPYRIGHT 2011 BY CH2M HILL, INC. • COMPANY CONFIDENTIAL

17. Tune the microwave generator to minimize the reflected power
18. Calibrate the THC Analyzer using 1000-ppm methane standard gas.
19. Record THC concentrations of inlet and outlet of Reactor 2 every 5 minutes
20. When THC concentration of Reactor 2 inlet decreases below 50-ppm, terminate microwave regeneration by shutting down microwave generators
21. Continue nitrogen flow to cool the regenerated GAC in Reactor 1 quartz tube but stop air flow to Reactor 2
22. When the temperature of Reactor 1 outlet gas decreases to about 100 °F, stop nitrogen flow and open the Reactor 1 quartz tube top
23. Open the bottom of Reactor 1 quartz tube to unload regenerated GAC and store this GAC in a clean bag
24. Regenerate remaining spent GAC by following Step 5 through 21
25. When all spent GACs in the first package are regenerated, drain liquid collected in the knockout pot
26. Measure the amount of liquid recovered from the microwave regeneration of spent GAC contained in the first package
27. Separate hydrocarbon and water by gravity
28. Save samples of recovered water and hydrocarbon liquid
29. Regenerate spent GAC in the second package following Step 1 through 24 described above
30. Two 60 gram samples (60 grams from each 10 lb batch) of regenerated GAC will be packaged separately and shipped to CH2M HILL's Applied Sciences Laboratory for residual TCE and iodine number analysis. These samples will be shipped to the address shown below:

CH2M HILL Applied Sciences Laboratory
Attn: Sample Receiving
2300 NW Walnut Blvd.
Corvallis, OR 97330-3588
541-752-4271

CH2MHILL will provide CHA the Iodine numbers and adsorption times for the TCE concentration of the adsorber outlet to reach 1 µg/L to measure the effectiveness of microwave regeneration of LGAC.

31. The regenerated GAC samples will be packaged separately and shipped back to CH2MHILL's project site by FedEx (2-day delivery) to the shipping address shown below:

4.0 REPORTING

CHA Corporation will prepare a brief technical memorandum describing the test work performed and summarizing the test procedure and results. The main goal of the microwave regeneration testing will be to demonstrate that microwave regeneration restores the GAC working adsorption capacity. The working adsorption capacity is defined as the adsorption capacity of regenerated GAC produced from the repeated adsorption and regeneration cycles. The working adsorption capacity may not be the same as the fresh GAC adsorption capacity. We need to conduct at least three cycles of adsorption and regeneration to find the working adsorption capacity of GAC. Consequently, two cycles of adsorption testing may not be sufficient to prove if the constant working adsorption capacity of GAC can be recovered by microwave regeneration. Three cycles of adsorption testing will produce results that will show the effectiveness of microwave energy for restoring constant working GAC adsorption capacity. The initial TCE breakthrough time will be closely related to GAC adsorption capacity. (Note: Two cycles of regeneration testing are included in the basic scope of work; a third cycle of regeneration testing is optional and will be authorized at CH2M HILL's discretion.)

It will not be possible to directly estimate the amount of energy used to dry wet spent GAC sample and the amount of energy used for the regeneration of dried sample from the fixed bed regeneration test results for application to a full-scale moving bed regeneration system. The fixed bed regeneration takes longer than the moving bed regeneration. Consequently, the fixed bed regeneration testing will not provide the energy data that can be directly scalable for use in estimating energy requirements for a full-scale regeneration system that utilizes moving bed regeneration. However, CHA Corporation can use test results from other recent test work to help estimate electric power requirements for a full-scale continuous microwave regeneration system as explained below.

Last year CHA Corporation conducted the field demonstration of microwave technology at Carson Energy site to remove siloxanes, hydrogen sulfide and hydrocarbons from biogas produced from Sacramento Waste Water Treatment Plant. The adsorption media saturated with water and hydrocarbons was regenerated by microwaves (Note: the GAC was saturated with water similar to the spent GAC from MMR). Several cycles of adsorption and regeneration were completed. During the field demonstration CHA Corporation has collected the electricity used for 6-hour microwave regeneration using one of two microwave reactors of the 100-lb/hr mobile microwave unit. Based on this field regeneration testing result and LGAC regeneration test results, we will calculate the energy requirement for regenerating one pound of carbon (on dry basis). Then, we will adjust the energy requirement for regeneration of higher moisture content GAC to estimate the power requirement for the full-scale microwave regeneration of the spent liquid phase GAC. We collected condensed water and hydrocarbons generated from the 6-hr microwave regeneration at 50-lb/hr regeneration rate during the field demonstration at Carson Energy site.

1.0 Introduction

CH2MHILL is currently operating a pilot-scale granular activated carbon (GAC) adsorption system at the Massachusetts Military Reservation (MMR) project site in order to generate spent GAC for pilot regeneration testing. The adsorption pilot test system consists of GAC columns (containing about 10 lbs of GAC each-dry basis) to treat an influent stream containing approximately 44 µg/L of TCE. The parallel pilot adsorption columns will be operated until the effluent concentration of TCE reaches 1 µg/L. Once the adsorption cycle is complete, spent GAC samples will be removed from two columns and shipped to the CHA Corporation Laboratory located in McClellan, California, for pilot microwave regeneration.

The first batch of spent GAC will consist of two separate 10 lbs (dry basis) samples of wet, spent GAC that must be tested separately. After microwave regeneration testing is completed, these samples will be shipped back to CH2MHILL MMR project site. The regenerated GAC samples will be re-loaded by CH2MHILL into their respective adsorption columns to repeat the adsorption cycle. After the second adsorption cycle is completed, the spent carbon will be sent back to CHA Corporation laboratory to repeat the microwave regeneration testing.

Prior to shipping the two 10 lb GAC samples back to the MMR project site, CHA Corporation will send approximately 60 grams of regenerated GAC from **each** 10 lb batch and after each subsequent regeneration cycle to CH2M HILL'S Applied Sciences Laboratory (ASL) so that they can be analyzed for the Iodine Number and the amount of residual TCE on the spent GAC. As requested by CHA Corporation, CH2MHILL will provide CHA the Iodine numbers and adsorption times for the TCE concentration of the adsorber outlet to reach 1 µg/L to measure the effectiveness of microwave regeneration of LGAC.

CHA Corporation has two microwave carbon regeneration units; 50-lb/hr pilot unit and 100-lb/hr mobile unit. It takes about 30 minutes for these microwave systems to reach a steady state operation. Consequently, 10 lbs of GAC sample is not sufficient amount for these microwave regeneration systems to be used for the microwave regeneration testing. The 100-lb/hr mobile unit has the microwave oxidizer that consists of two microwave reactors. This microwave oxidizer unit can be disconnected from the mobile microwave trailer and modified for testing the 10-lb samples as a fixed bed reactor. The first microwave reactor will be used to regenerate spent carbon and the second microwave reactor will be used to oxidize TCE vapor desorbed from spent carbon. Dr. C.Y. Cha discussed this possibility with Mr. Mike Grigorieff and obtained his agreement using these two microwave fixed beds for regeneration testing.

The main objective of microwave regeneration testing of LGAC is to evaluate the feasibility of regeneration of spent GAC using a microwave-based regeneration process at the MMR project site. The first step for this feasibility evaluation is to demonstrate that the microwave regeneration will restore the GAC adsorption capacity. Also, it is our goal to demonstrate that the microwave oxidation of VOCs generated from the regeneration will be oxidized at low temperature completely, resulting in no air emission during regeneration operation. We will assist CH2MHILL to see if it can be demonstrated that the microwave-based regeneration of spent GAC at one of the MMR project sites is more economical than off-site thermal regeneration currently being used.

2.0 System for Microwave Regeneration Pilot Testing

Figure 1 shows the microwave oxidizer that was originally constructed to oxidize waste gasses generated during the reactivation of biogas saturated carbon.

Figure 1: Picture of Microwave Oxidizer Prior to Modification

The piping for this unit was modified to perform the regeneration tests. Nitrogen gas was piped into the top of the first reactor. The exhaust from this reactor exits the bottom of the reactor and enters a water cooled double pipe condenser. The condensed liquid is separated from the vapor stream in the knockout. The vapor continues to the bottom of the second reactor, which is packed with a mixture of granular silicon carbide and oxidation catalyst. Air is also added to the bottom of this reactor. The non-condensable hydrocarbons are oxidized in the second stage and exhausted from the system. The hydrocarbon concentration measured at the inlet and outlet of the second reactor to calculate the oxidation efficiency. The process flow diagram for the system is shown in figure 2, and photos of the modified system are shown in figures 3 and 4.

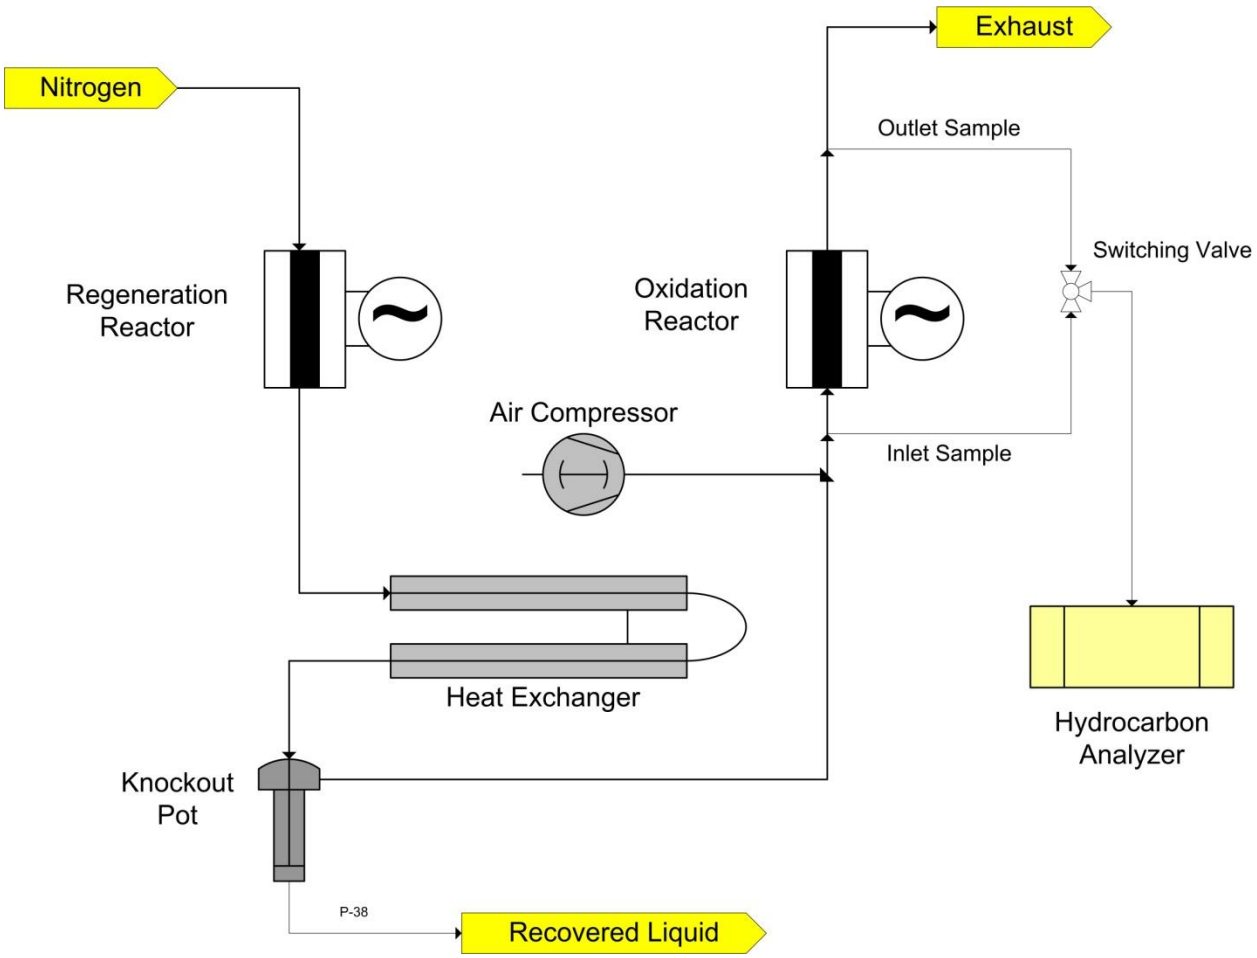

Figure 2: Test System Process Flow Diagram

3.0 Testing Methodology

MICROWAVE REGENERATION TESTING PROCEDURE

Two spent GAC samples sent by CH2MHILL will be stored in the refrigerator until the microwave regeneration testing facility is ready. Below is the step by step procedure for microwave regeneration testing for each 10-lb sample (on dry basis) of spent liquid phase GAC.

1. Unpacked the first spent GAC sample package
2. Measure the weight of spent GAC.

3. Measure the moisture content of the GAC by drying about 100 g samples at 100 °C overnight.
4. Check Reactor 2 to make sure that the quartz tube contains the mixture of 50% SiC and 50% Pt-based oxidation catalyst
5. Open the top of the quartz tube of Reactor 1
6. Fill the quartz tube with spent GAC close to the top
7. Measure remaining spent GAC to estimate the weight of spent GAC loaded in Reactor 1
8. Close the top of quartz tube
9. Start nitrogen sweep gas flow and set its rate at 1.5-scfm
10. Check for the gas leakage around Reactor 1 and Reactor 2 using soap bubble-water.
11. Start chiller and microwave cooling water pump
12. After the nitrogen flow is stabilized, start Reactor 2 microwave generator and set the microwave power at about 2.7-kW or 90% of the power level
13. Tune the microwave generator to minimize the reflected power using the tuner.
14. Start air flow to Reactor 2 and set its flow rate at 0.5-scfm
15. Preheat Reactor 2 for 30 minutes
16. After 30 minutes, start Reactor 1 microwave generator and set the microwave power at 90%
17. Tune the microwave generator to minimize the reflected power
18. Calibrate the THC Analyzer using 1000-ppm methane statandard gas.
19. Record THC concentrations of inlet and outlet of Reactor 2 every 5 minutes
20. When THC concentration of Reactor 2 inlet decreases below 50-ppm, terminate microwave regeneration by shutting down microwave generators
21. Continue nitrogen flow to cool the regenerated GAC in Reactor 1 quartz tube but stop air flow to Reactor 2
22. When the temperature of Reactor 1 outlet gas decreases to about 100 °F, stop nitrogen flow and open the Reactor 1 quartz tube top
23. Open the bottom of Reactor 1 quartz tube to unload regenerated GAC and store this GAC in a clean bag
24. Regenerate remaining spent GAC by following Step 5 through 21
25. When all spent GACs in the first package are regenerated, drain liquid collected in the knockout pot
26. Measure the amount of liquid recovered from the microwave regeneration of spent GAC contained in the first package
27. Separate hydrocarbon and water by gravity

28. Save samples of recovered water and hydrocarbon liquid

29. Regenerate spent GAC in the second package following Step 1 through 24 described above

30. Two 60 gram samples (60 grams from each 10 lb batch) of regenerated GAC will be packaged separately and shipped to CH2M HILL's Applied Sciences Laboratory for residual TCE and iodine number analysis. These samples will be shipped to the address shown below:

4.0 Test Results

The primary results from the testing are the material balance data, which were generated by weighing the mass of the carbon going into the bed, and the mass after regeneration. That data is presented in the following section.

4.1 Material Balance Data

Table 1 shows the masses collected during the regeneration of the first batch of saturated GAC. The percent of weight lost over all of the tests was 46%.

Table 1: Material Balance from the First Test Cycle

Summary Table										
	R1	R2	R3	R4	R5	R6	R7	R8	R9	Total
Starting Mass (lb)	4.2	4.9	4.7	4.8	4.55	4.65	4.65	4.65	0.15	37.25
Regenerated Mass (lb)	2.4	2.5	2.55	2.55	2.45	2.45	2.4	2.4	0.5	20.2
Liquid Recovered (lb)	1.55	1.8	1.7	1.7	1.65	1.7	1.7	2.05	0.05	13.9
Percent Weight Loss	43%	49%	46%	47%	46%	47%	48%	48%	NA	46%

Figure 5 is a graphical presentation of the data contained in table 1. The data for the first run shows a slightly lower liquid recovery than subsequent runs. This is probably due to the carbon at the top of the bucket being dryer than at the bottom. After the first run, the bucket was turned upside down for 10 minutes prior to removing the sample, to redistribute the moisture more evenly. Runs 2 through 7 show very consistent behavior due to the even moisture distribution. Run 8 shows a higher moisture content than the other samples, and the amount of carbon left for run 9 was not enough to get accurate weights.

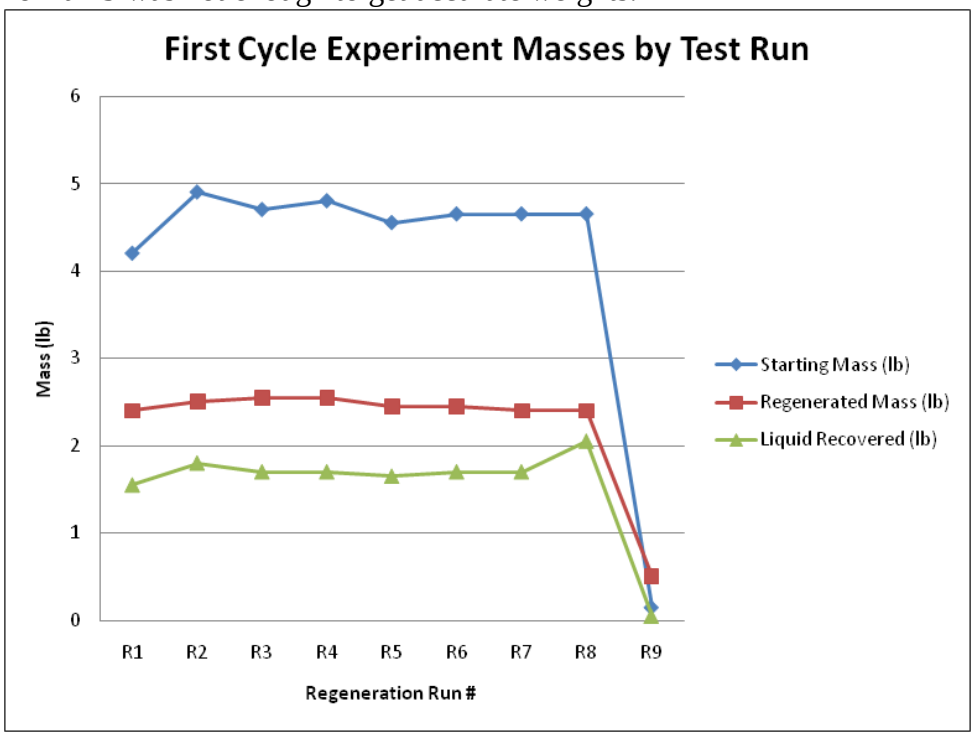

Figure 5: First Cycle Mass by Run

For the second cycle, the material was returned to us in two batches. We denoted this as C3 and C4, and they were kept separate throughout testing. The initial weight of C3 was 21.14 lb and the initial weight of C4 was 15.17 lb. During regeneration C3 lost 47% of its weight, and C4 lost 46%. The data for each run is summarized in Table 2, and Graphically presented in Figure 6.

Table 2: Material Balance from the Second Test Cycle

Summary Table												
	C3 R1	C3 R2	C3 R3	C3 R4	C3 R5	C3 R6	C4 R1	C4 R2	C4 R3	C4 R4	C3 Total	C4 Total
Starting Mass (lb)	3.15	3.71	3.77	4.07	3.93	2.51	3.94	4.16	3.35	3.72	21.14	15.17
Regenerated Mass (lb)	1.80	2.08	2.05	2.14	1.95	1.20	2.20	2.23	1.89	1.93	11.22	8.25
Liquid Recovered (lb)	1.16	1.45	1.51	1.70	1.72	1.13	1.49	1.59	1.36	1.57	8.67	6.01
Percent Weigh Loss	43%	44%	46%	47%	50%	52%	44%	46%	44%	48%	47%	46%

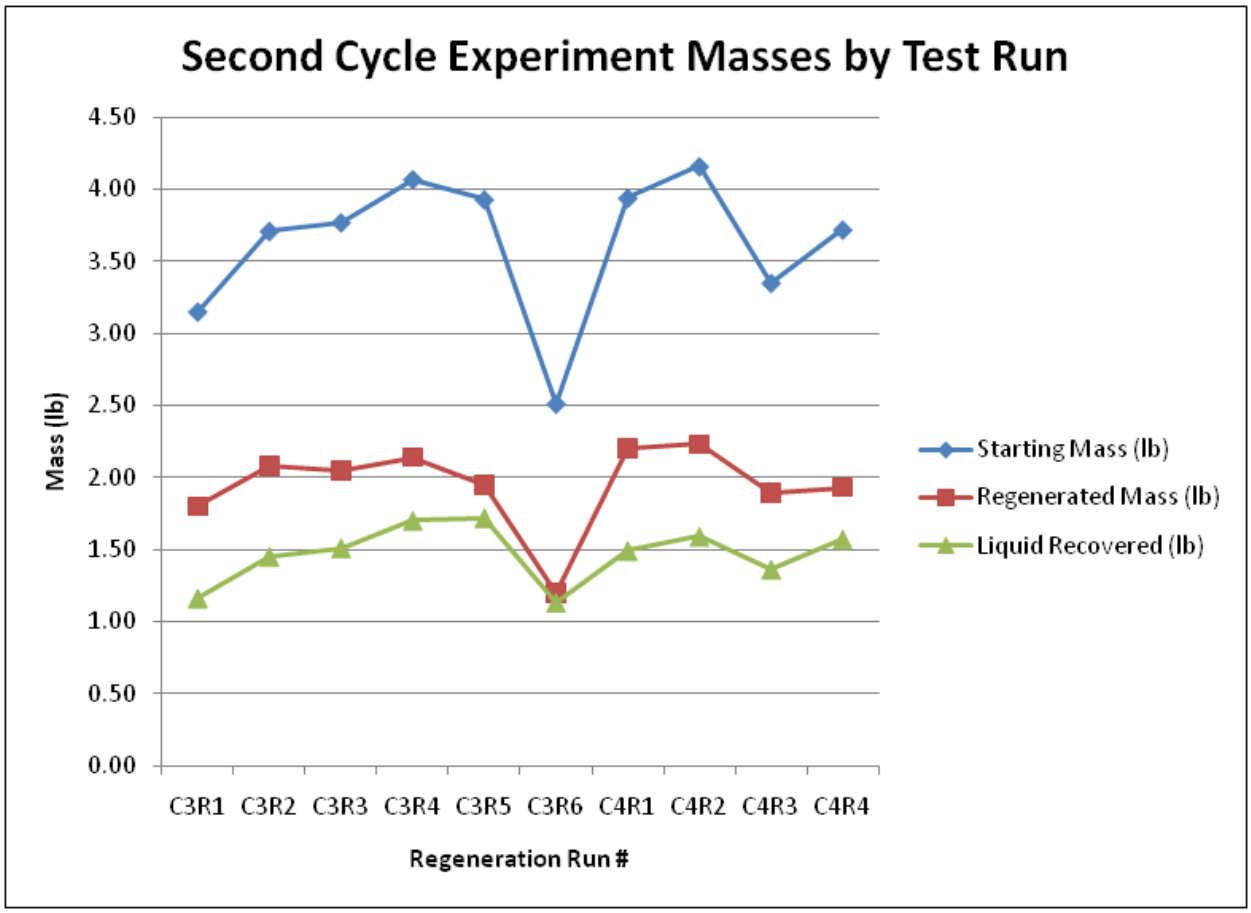

Figure 6: Material Balance for the Second Test Cycle, Seperated as C3 and C4

The test data for C3 is a little more erratic than what was seen in the first cycle of testing. It appears that turning the bucket upside-down was not sufficient to evenly redistribute the water, as the weight loss increased by run. The average weight loss over the test was 47%. The data for C4 was somewhat smoother. The average weight loss was 46%. These weight losses are consistent with what was recovered during the first test.

5.0 Conclusions

The results from the first two test cycles have been encouraging. They clearly demonstrate that the activated carbon is regenerated to a stable working capacity. It is not possible to directly correlate the energy usage from the laboratory tests to a full scale system. Because of insufficient amount of saturated GAC samples, we could not use the 50-lb/hr pilot unit. The microwave pilot unit is a moving bed but the laboratory microwave unit is a fixed bed. Knowing what the moisture content is and using our previous data from regenerating other saturated carbons, we can estimate the power required for the system.

Because there is so much moisture in the carbon, a pre-drying step should be considered. Using hot air, the carbon can be heated to ~250 F. For a 100 lb/hr system with moisture content of 48%, the energy required for drying is ~ 14kW. The dried, preheated carbon then enters the microwave regenerator at a rate of 52 lbs/ hr. 6-kW of microwave power is applied to regenerate the carbon. Microwave generators are approximately 80% efficient, so the electric power required is approximately 7.5-kW. The refrigerated chiller and other ancillary equipment use another 8-kW of power. The total power usage of the process is 29.5-kW for the 100 lbs of wet GAC per hour microwave regeneration system.

APPENDIX E

GAED Test Reports

GAED Full Characterization of
Regen Pilot Test 2-7-11 1350 (AA-467) and
Regen Pilot Test 2-7-11 1330 (AA-468)
February 28, 2011

Executive Summary

Two samples of granular activated carbon (GAC) were fully characterized using the Gravimetric Adsorption Energy Distribution method (GAED): Regen Pilot Test 2-7-11 1350 (AA-467) and Regen Pilot Test 2-7-11 1330 (AA-468). The samples were compared to three commercially available activated carbon reference samples: BPL a Coal-based gas phase, CAL a Coal-based liquid phase and PCB a Coconut-based carbon. Both samples lost less than 1½ weight percent on conditioning (heating the samples to 240ºC under argon and holding for 25 minutes) indicating they were clean and dry. Sample (AA-467) showed about 3½% greater total adsorption pore volume than AA-468. However, the differential characteristic curves show both samples to exhibit more large-pore-volume, which can be a characteristic of reactivated material. The calculated BET surface area showed that sample AA-467 was 713 sq.meters/g. and sample AA-468 was 691 sq.meters/g. Aqueous phase isotherms and reference samples were used in this analysis to showed how these two materials compared in the adsorption of MTBE, Benzene and Phenol. The Applications Performance graphs are included and show these two samples did well in a variety of applications. Microscopic photographs of these samples are available upon request.

GAED Results:
Samples Regen Pilot Test 2-7-11 1350 (AA-467) and Regen Pilot Test 2-7-11 1330 (AA-468) were fully characterized by measuring the entire characteristic curves using the GAED. The Apparent Densities (AD) of 0.561 g/cc and 0.531 g/cc were used allowing volume-based results. The carbons were then compared to three commercially activated reference samples made from a range of raw materials.

PACS Sample ID		Client Sample Identification
AA-467	Unused CSR GAC	Regen Pilot Test 2-7-11 1350
AA-468	Round #2, Microwave Regenerated	Regen Pilot Test 2-7-11 1330
BPL Coal-base gas phase		
CAL Coal-base Liquid phase		
PCB coconut-base		

The samples were run in granular form. A summary of the actual test data and conditions used is listed in the data summary table at the end of the report in Appendix A. The AA-467 sample lost 1.18 weight percent and the AA-468 sample lost 1.47% on conditioning (heating to 240ºC in argon and holding for 25 minutes). Losses of less than 8 percent indicated a well-stored sample that had been protected from the small amount of moisture pick-up from ambient air during handling and storage and was also fresh and not oxidized. Both samples lost a relatively small amount of weight indicating they were protected (stored in a proper container) from oxidation or picking up humidity. All

activities and adsorption capacities were calculated on a clean carbon basis. To observe these capacities in the field may require additional processing of the carbon on site.

The GAED runs were typical. The difference between the adsorption and desorption curves were minor throughout the experiment; therefore there was no hysteresis present, as is normal for commercially activated carbons. This report extended the comparison of these carbons beyond just the presentation of the characteristic curves. The plots of the differential and cumulative characteristic curve data are presented in Figures 1 and 1b in a volume-based comparison. Weight-based comparisons are also available. The specific run data and results are attached as Appendix A.

GAED Raw Data

The GAED (gravimetric adsorption energy distribution method) measured over 400 adsorption and desorption data points covering seven orders of magnitude in relative pressure (isothermal basis) and three orders of magnitude in carbon loading. The mass adsorbed was also divided by the carbon mass to generate a weight percent loading for easier comparisons. The raw data is plotted in Figure 2. At 240ºC, the adsorbent gas C134a or 1,1,1,2-tetrafluoroethane was introduced and the loading increased. Note in Figure 2, the mass loading was plotted against temperature but the relative pressure was also changing. There were three variables affecting performance that changed from point to point: vapor pressure, partial pressure, and temperature.

To make comparisons easier, the large data file of adsorption/desorption points at different temperatures and relative pressures was simplified. First the data was interpolated to get 30 evenly spaced points covering the entire data range. Next the adsorption and desorption results were averaged to get the equilibrium values (the difference between adsorption and desorption was minimal for this sample - no hysteresis). The y-axis was converted to pore volume measures, in cc liquid adsorbed or cc pores filled/100grams carbon, instead of weight percent. The average interpolated data for these characteristic curves is presented in Table 1, and Figures 1a and 1b.

Performance Prediction Models

These curves were the only carbon related information required to predict physical adsorption performance using Polanyi Adsorption Potential theory. These single and multicomponent, gas and liquid phase, computer models were used to predict carbon performance and are available from PACS. To do performance predictions the following polynomial describes these carbon samples:

Carbon name	**Characteristic curve polynomial - 3rd degree**
AA-467	y = 2.8137E-05x3 - 1.8084E-03x2 - 3.0526E-02x + 1.6077E+00
AA-468	y = 4.2447E-05x3 - 2.4102E-03x2 - 2.4294E-02x + 1.5830E+00
BPL Coal-base gas phase	y = 5.8955E-05x3 - 2.8880E-03x2 - 2.6182E-02x + 1.7029E+00
CAL Coal-base Liquid phase	y = 3.5299E-05x3 - 1.8375E-03x2 - 4.0325E-02x + 1.6682E+00
PCB coconut-base	y = 5.6334E-05x3 - 3.0968E-03x2 - 1.3312E-02x + 1.6731E+00

In the equation, **y** was the common logarithm of pore volume in cc/100g carbon and **x** was the e/4.6V adsorption potential in cal/cc. Characteristic curve polynomials are also listed in Appendix A.

Performance in the Six Types of Applications

The simplest comparison of carbon for a specific application was to run the performance prediction calculations for specific conditions, concentrations, and components present in the application. However, our experience with years of carbon optimization and performance comparisons has found that all physical adsorption applications can be placed into six application types. The proof is part of a 16-hour/800 slide-training course on carbon fundamentals given by PACS at least once a year.

The comparative results in Table 2a demonstrate the value of the different carbons for use in the different types of applications on a volume basis. For a given application type, the results were related to the amount of carbon required to get a certain level of performance. Therefore, a carbon with twice the cc/100g adsorption performance in an application type required half the pounds of carbon to achieve a level of performance in that application type.

Table 2a compares performance on a volume basis and gives the values of the comparative results for the sample carbons versus the performance for the standard commercial carbons for the six application types. These results can also be provided on a weight basis if desired.

A series of two slides are attached as Appendix B, which describe the 6 application types and the classification process to determine what was the application type. Wastewater applications tend to be Type II or Type III. Municipal water purification varied from Type III, Type IV or Type V applications. Removal limits are not low enough and analytical testing is not sensitive enough at this date for Type VI. (Purifying hydrogen of CO and N2 at room temperature is one of the few current Type VI applications). Municipal plants with surface water sources tend to be Type III or Type IV. Plants with ground water sources tend to be Type IV or V.

Trace Capacity Numbers

The characteristic curves were used to predict the values for the acetoxime trace capacity (TCN), gas-phase trace capacity number (TCNG) and mid capacity number (MCN). These results are presented at the bottom of the summary pages in Appendix A.

Adsorption Isotherms

The characteristic curves were also translated into adsorption isotherms using the programs mentioned above: Figure 3 for MTBE (weakly adsorbed material), Figure 4 for benzene (more strongly adsorbed species) and Figure 5 for phenol at pH=7 (quite strongly adsorbed material).

Pore Size Distributions

The Kelvin equation, modified by Halsey, can be used to convert the characteristic curve data to calculated BET surface areas or pore size distributions. This was not useful in terms of performance evaluations, but some audiences are more comfortable with the concepts of pore radius and a series of capillary sizes when thinking about activated carbon. Figure 6 shows the cumulative pore size distributions, which we included but find of little use. The single and multi point BET surface area was calculated from these curves and is presented in the Summary Tables in Appendix A.

Interpretation of the GAED results:

1. Two samples were fully characterized using the GAED: Regen Pilot Test 2-7-11 1350 (AA-467) and Regen Pilot Test 2-7-11 1330 (AA-468).
2. The samples were compared to three commercially available activated carbon reference samples: BPL Coal-based gas phase, CAL Coal-based liquid phase and PCB Coconut-based carbon of about 1200-iodine number.
3. The samples lost less than 1.2 and 1.5 weight percent on conditioning indicating they had not picked up contaminates like humidity or an oxidizing substance (Data Summary Table Appendix A).
4. Conditioning entailed heating the samples to 240ºC under argon and holding for 25 minutes so that all calculations were done on a clean basis.
5. The conditioned Regen Pilot Test 2-7-11 1330 (AA-468) showed slightly greater pore structure from the 26 to 29 cal/cc energy level than AA-467; however the better material of the two samples was Regen Pilot Test 2-7-11 1350 (AA-467) by about 3½% total adsorption pore volume (Table 1).
6. Both of the conditioned samples were about 8% below CAL, the Coal-based liquid phase reference material, in total adsorption pore volume (Table 1).
7. However, of interest are the differential characteristic curves, which show both the samples to exhibit more large- pore-volume, which can be a characteristic of reactivated material (Figure 1b).
8. Aqueous phase isotherms showed how these two materials compared in the adsorption of MTBE, Benzene and Phenol (as shown in Figures 3, 4 and 5).
9. Calculated BET surface area indicated 713 sq.meters/g. for Sample 1 (AA-467), and 691 sq.meters/g for Sample (AA-468) (Data Summary Table Appendix A).
10. Graphs of the six Application Performance Types are included and showed that both samples AA-467 and AA-468 performed well in all types: Type I Regenerable Heavy Loading Applications like Butane Working Capacity, Type II Heavy Loading Applications like p-Nitrophenol from Water, Type III (Moderate Loading Applications like Benzene Vapor from Air), Type IV (Regenerable Trace Loading Applications like Acetone Solvent Recovery), Type V (Trace Loading Applications like Trichloroethane from Water) and Type VI (Ultra Trace Loading Applications like Vinyl Chloride from Water).
11. Microscopic photographs of these samples are available upon request.

☒	General Project Note	Recorded By:	Brad Johnson, Project Engineer
Subject:	**ON-SITE GRANULAR ACTIVATED CARBON REGENERATION PILOT TEST STATUS UPDATE**	Issued By:	Patricia de Groot CH2M HILL PROGRAM MANAGER

ITEM	REMARKS
1.0	**PURPOSE & BACKGROUND** The purpose of this project note is to provide an update on the two ongoing pilot studies for onsite granular activated carbon (GAC) regeneration for the Air Force Center for Engineering and the Environment (AFCEE) at the Massachusetts Military Reservation (MMR). The two treatment technologies being evaluated include: • Hot water desorption with advanced hydrogen peroxide/ultraviolet (UV) light oxidation process (AOP) for destruction of desorbed volatile organic compounds (VOCs); and • Microwave GAC regeneration. The first round of GAC regenerations was completed in July 2010 and the second round was completed in January 2011.
2.0	**RECENT RESULTS** As of 31 January, 2011, the batches of GAC had been regenerated by the microwave and hot water desorption-based processes for the second time. The results of the microwave regeneration for second round were similar to those from the first round. Approximately 94% of the trichloroethene (TCE) was measured as removed for the first round of microwave regeneration. For the second round, approximately 99% of the TCE was measured as removed. The results of the hot water regeneration for second round were also similar to those from first round, despite the process modifications made for the second round. For the second round, the hot water desorption process was modified to include fluidization of the GAC bed during the desorption process to improve mass transfer from the GAC into the desorption water. Additionally, separate hot water rinses were performed to evaluate whether potential buildup of TCE in the rinse water may have been inhibiting additional desorption. Each rinse round was fluidized and recirculated through the column for 24 hours at 150˚F.

Distribution: AFCEE: Rose Forbes, Admin. Record
CH2M HILL: Pat de Groot, Brad Johnson, Mike Grigorieff, Karen Meade, Doc. Control

ITEM	REMARKS
	Previously, approximately 4% of TCE was measured as removed during the first round of regeneration. For the second round of regeneration with the modifications, also approximately 4% of TCE was measured as removed. For the first rinse of the second round of regeneration, approximately 4% of TCE was measured as removed. For the second rinse of the second round of regeneration, an additional approximately 0.4% of TCE was measured as removed. These column test results indicate that TCE is not being effectively desorbed from the GAC by the hot water desorption process. Due to previous jar tests results that indicated better desorption of TCE with hot water, additional jar testing was performed to evaluate the hot water desorption (costs associated with this work not charged to AFCEE). These additional jar test results were similar to the results seen in the column test for this second round of regeneration, thus indicating poor desorption with hot water based on the hot water desorption processes tested to date. The discrepancy between previous jar test results (which showed good desorption) and the additional jar test results (showing poor desorption) is likely due to modifications of the analytical method used to measure TCE loading on the GAC. The most recent method of extraction developed at Applied Sciences Laboratory (ASL) is a multi-step process requiring a 24-hour contact time, and has been shown to be effective at fully recovering the adsorbed TCE from spent GAC. Previous versions of the extraction method utilized a single step process employing either methanol or carbon disulfide as the extraction solvents. In both cases, the extraction efficiency was limited by the contact time of the solvent and the single step processing. Older jar test results were therefore not accurately measuring the TCE on the GAC before and after desorption. This resulted in the desorption appearing to be more effective than it actually was.
3.0	**RECOMMENDATIONS** Based on these findings, CH2M HILL recommends not continuing with further evaluation of the batch of hot water-desorbed GAC in the Chemical Spill-10 In-Plume pilot test system due to the ineffectiveness of the process as currently designed in desorbing TCE from the spent GAC. This will eliminate shipping costs to return the GAC to the Massachusetts Military Reservation (MMR) from ASL in Corvallis, eliminate costs associated with analysis of water samples from these pilot test columns, and eliminate the costs of specialized GAC analyses by PACS (GAED and iodine number testing) on the regenerated GAC. All work on the microwave-regenerated GAC will still proceed as planned, and the pilot test will be wrapped up by the end of the Task Order (TO)-0175 period of performance. In order to further develop the hot water desorption process, CH2M HILL proposes running a continuous column test that would better mimic the full-scale concept. However, instead of using an advanced oxidation process (AOP) for continuous destruction of TCE (which would be very difficult to achieve in a pilot-scale system), we propose air stripping the TCE from the hot

ITEM	REMARKS
	water before it is recirculated through the column. We hypothesize that the amount of TCE desorbed with each hot water pass is very small and that clean water is needed for this desorption to occur. Air stripping would provide a straightforward way to remove the TCE from the water being recirculated without the need to manage the AOP (which would require careful control of hydrogen peroxide concentrations depending on TCE concentrations). The water would be recirculated and treated for a period of time (e.g., 48 hours). The GAC would be analyzed after 48 hours to determine how much TCE was desorbed. It is proposed that this work be performed under TO-0244. A work plan, and labor and materials estimate will be provided to AFCEE for approval prior to proceeding with any further development of the hot water desorption process. If the results of this follow-on work result in effective desorption of TCE from the spent GAC, then the GAC would be returned to MMR for bed life testing in the pilot column system, followed by an evaluation of the economic and sustainability impacts of implementing the technology at full-scale. This work would be done under a future task order.

☒ General Project Note	Authored By: Brad Johnson P.E., Project Engineer
Subject: **Pilot Column Performance Test of Alternative Granular Activated Carbon Products**	Issued By: Patricia de Groot, P.G.  CH2M HILL PROGRAM MANAGER

ITEM	REMARKS
1.0	**PURPOSE** The purpose of this project note is to describe the results of a performance comparison test of three different commercially available granular activated carbon (GAC) products versus a reactivated coal-based GAC product currently used at groundwater treatment facilities owned by the Air Force Center for Engineering and the Environment (AFCEE) at the Massachusetts Military Reservation (MMR). This testing was designed to determine if alternative GAC products may exhibit longer bed lives than the currently used reactivated coal-based product. Longer bed life would result in fewer GAC exchanges, which in turn could reduce annual operating costs for the GAC treatment systems and improve the overall sustainability of the groundwater treatment program at the MMR.
2.0	**TECHNICAL APPROACH** A ten-column pilot test system (Figures 1 and 2) was built at the Chemical Spill 10 In-Plume (CS-10 IP) Building D treatment plant. Four of the ten columns were used for this testing[1]. The four columns were filled with the following different types of GAC: Column A: Custom segregated reactivated (CSR) coal-based GAC supplied by Carbon Activated Corp. Column B: Virgin coconut-based GAC supplied by Carbon Activated Corp. Column C: Filtrasorb 600 virgin coal-based GAC supplied by Calgon Corp. Column D: Hydrodarco 4000 virgin lignite-based GAC supplied by Norit Americas, Inc. The CSR GAC is the product currently used by AFCEE and is the control for this test. Coconut-based GAC is normally used in vapor phase applications, but it is sometimes used for removal of trace concentrations of contaminants, similar to the applications at MMR. The virgin coal-based Filtrasorb 600 is a commonly used product in groundwater remediation applications.

[1] The other six columns were used for testing GAC regenerated by microwave and hot water desorption methods.

Distribution: AFCEE: Rose Forbes; CH2M HILL: Pat de Groot, Drew Tingley, Doc. Control

ITEM	REMARKS
	Lignite-based GAC is generally used in potable water applications for removal of VOCs. The columns were supplied with common contaminated influent water from the CS-10 IP Building D treatment plant influent. Each column was equipped with two mid-bed sample ports and an effluent sample port to allow for progress of the contaminants through the beds to be monitored by sampling and analysis. All four columns were to run until the concentration of trichloroethene (TCE) in the effluent of each column exceeded the GAC exchange criteria of 1 microgram per liter (µg/L). By evaluating the time required for each column to exceed the GAC exchange criteria, a quantitative comparison of the performance of each type of GAC could be made. All four products consisted of granules in the 12x40 mesh size range. Each 4-inch inside diameter column was filled with 66 inches (approximately 15 pounds dry weight) of GAC. The influent flow rate into each column was set to 0.5 gallons per minute (gpm). This results in an empty bed contact time (EBCT) of nine minutes, which is approximately the same EBCT that occurs in the full-scale carbon vessels when operating at the current design flow rate of 570 gpm. Samples of groundwater passing through the columns were taken at bi-weekly (every other week) intervals. Samples were collected at the common influent, the upper mid-bed sampling ports (located 4 feet above the column base; refer to Figure 1), the lower mid-bed sampling ports (located 2 feet above the column base downstream of the first sampling port), and the column effluent ports. Samples were analyzed for volatile organic compounds (VOCs) by Environmental Protection Agency Method 8260b at Analytics Environmental Laboratory, LLC of East Portsmouth, New Hampshire.
3.0	**RESULTS**
3.1	**First Detections of TCE** The pilot test system was operated for a total of 482 days; beginning on 26 January 2010 and ending on 23 May 2011. VOC concentration data is provided in Table 1. Figures 3 through 6 graphically depict TCE concentrations over the course of the test. Figure 3 shows a graph of TCE concentration in the common influent. Influent TCE concentrations varied between 36 and 50 µg/L over the course of the testing. Figures 4 through 6 show graphs of TCE concentrations measured at the upper mid-bed, lower mid-bed, and effluent sample ports in each of the test columns. The first column to show a detection of TCE in the upper mid-bed sample port was the Hydrodarco 4000 lignite; 0.19 µg/L on 03 March 2010 after 36 days of operation. The last column to show a detection of TCE in the upper mid-bed sample port was the virgin coconut; 0.47 µg/L on 04 August 2010 after 190 days of operation.

ITEM	REMARKS

It is noted that at times, analyses indicated that TCE concentrations in the columns were higher than the influent concentration. This effect can occur when the influent concentration to a fully saturated bed of GAC drops, causing desorption of contaminant from the saturated GAC. The result is that the mid-bed or effluent concentration may be higher than the influent concentration. This effect dissipates with time provided the influent concentration does not continue to drop.

3.2 Flowmeter Accuracy

After approximately 160 days of operation, the TCE concentrations in the upper mid-bed sample ports of the Hydrodarco 4000 and the CSR were both 26.0 µg/L, while the concentrations at this port in the column containing the virgin coal product was only 1.4 µg/L and TCE had not yet been detected at all at this port in the column containing the virgin coconut product. Since such a wide range of performance was not expected, the calibration of the flowmeters in each column was checked to ensure that each column was actually receiving the same amount of water. The effluent of each column was temporarily redirected into a graduated cylinder and the actual flow rate from each column was calculated from the time it took to fill the measured volume. This test indicated that three out of the four flowmeters had deviated significantly from their advertized accuracy of ±0.1 gpm. While all four flowmeters indicated the design flow rate of 0.5 gpm, the actual flow rates through the four columns were as follows:

Column A (CSR):	0.17 gpm
Column B (virgin coconut):	0.31 gpm
Column C (Filtrasorb 600):	0.33 gpm
Column D (Hydrodarco 4000):	0.52 gpm

After identifying the flowmeter inaccuracies, the flowmeters (Blue White Industries F-450 series rotameters) were disassembled and examined. It was noted that a thin film (possibly biogrowth judging from its appearance and consistency) had formed on the internals of the flowmeters. The flowmeter readings had been checked every day by O&M staff and only small adjustments had been made to the flow control valves as necessary to ensure the flowmeters were registering the design flow rate. The floats inside the flowmeters consequently had been in virtually the same position since the start of the test approximately 160 days previously and this film had formed on the floats and shafts, which reduced the ability of the floats to move freely with changes in flow rate. The result is that several of the flowmeters were stuck at an artificially high flow reading.

ITEM	REMARKS
	In order to prevent recurrence of this problem, beginning on 15 July 2010, the flowmeters were "exercised" daily by briefly opening up the flow control valve and then closing it several times to allow the flowmeters to go all the way up to the full scale reading and then all the way to the bottom of the scale, thereby scraping any buildup of material off the shaft and float. Calibration of the flowmeters was rechecked several times over the remainder of the test program, and calibration was found to be within factory specifications, so this technique appeared to be effective in maintaining flowmeter accuracy. In order to utilize data obtained prior to the discovery of the flowmeter inaccuracies, the data were adjusted based on an assumed constant rate of change in the accuracy of the flowmeter readings. It was assumed that the flowmeters read accurately at the beginning of the test on 26 January 2010, so the actual flow rate through each of the four columns was assumed to be 0.5 gpm at the beginning of the test. Since the flowmeter inaccuracies appeared to be caused by buildup of a thin film of material on the floats and rods, an assumption was made that the actual flow rates through the four columns decreased in a more or less linear fashion between the beginning of the test and the discovery of the inaccuracies after approximately 160 days of operation. The change in VOC concentrations from one sample event to the next were therefore adjusted in proportion to the ratio between the assumed actual flow rate on any given sample date and the design flow rate of 0.5 gpm per column. These adjustments were continued until the adjusted VOC concentrations in the upper mid-bed sample ports reached the measured VOC concentrations in the upper mid-bed sample ports, indicating that corrections of the data were no longer necessary. The data in Table 1 subsequent to this time (which occurred after approximately 218 days of operation) are the actual VOC results. The data in all figures are taken from Table 1, so these figures display corrected data. Applying this data correction method did not substantially change the results of this testing in comparison to the uncorrected data. The uncorrected data showed all columns exceeding the 1 µg/L effluent concentration at the same time as the corrected data.
3.3	**Exceedance of GAC Exchange Criteria** Figure 6 indicates that the first column to exceed the GAC changeout criteria of 1 µg/L at the effluent was the Hydrodarco 4000 lignite; 1.20 µg/L on 18 August 2010 after 204 days of operation. The column containing the virgin coconut GAC exceeded the GAC changeout criteria after 456 days of operation on 27 April 2011 with an effluent concentration of 1.7 µg/L. For comparison, the CSR GAC effluent exceeded 1 µg/L after 218 days of operation. The order of progression of TCE concentrations through the four columns remained more or less unchanged throughout the course of the testing. The Hydrodarco 4000 exhibited the shortest bed life, followed by the CSR and the Filtrasorb 600 virgin coal respectively. The longest bed life was exhibited by the virgin coconut shell product.

ITEM	REMARKS
4.0	**CONCLUSIONS & RECOMMENDATIONS** Based on the results of this pilot testing, it appears that a doubling of bed service life may be possible by switching to virgin coconut shell-based GAC from the currently used CSR GAC. One important difference between the pilot test and full-scale operation is that in full-scale operation, after a GAC exchange the fresh GAC is initially used in the lag position of the GAC train. During this time, low levels of contaminant (generally no more than 1-2 µg/L) eventually begin to pass through the lead GAC vessel as the GAC in that vessel becomes loaded. This contamination enters the lag vessel where it is adsorbed by the fresh GAC. When the lead vessel effluent concentration exceeds the GAC changeout criteria, the lead vessel GAC is exchanged and the lag vessel (which has already been treating low levels of contamination in the lag position) is switched to the lead position. However, in the pilot test setup, the GAC in all columns had not been exposed to any contaminant at the start of the test. This difference between pilot-scale and full-scale operation is not expected to make results of the pilot test not directly transferrable to full-scale operation. Based on interim results from this pilot test, on 26 August 2010 CH2M HILL recommended to AFCEE that a full 20,000-pound load of virgin coconut shell-based GAC be installed in one of the GAC vessels at CS-10 IP Building D in order to directly compare bed life of this product to CSR GAC at full-scale. This load of GAC was installed in the lag position on 14 December 2010, and it was subsequently switched into the lead position on 18 February 2011. The service life of this GAC in the lead position will be compared to the average service life of GAC beds at this plant in order to evaluate the use of this product in the full-scale application. CH2M HILL also recommends that a financial feasibility analysis and sustainability analysis be performed to compare the use of virgin coconut shell-based GAC to the currently used thermally reactivated GAC in order to determine if it may be advantageous to AFCEE to implement use of this product at full-scale at treatment plants where TCE controls GAC exchanges. This work would be completed under a future task order.

Subject: **TEST OF PERMANGANATE PRETREATMENT AT THE SANDWICH ROAD TREATMENT FACILITY**	Issued By: Patricia de Groot, P.G. CH2M HILL PROJECT MANAGER

ITEM	REMARKS

1.0 INTRODUCTION

The purpose of this project note is to present the results of a test of the injection of potassium permanganate ($KMnO_4$) into the influent stream at the Sandwich Road Treatment Facility (SRTF) at the Massachusetts Military Reservation (MMR). This testing was undertaken to determine if the concentrations of contaminants entering the SRTF (primarily trichloroethene [TCE]) could be decreased by the process of chemical oxidation using $KMnO_4$ as a pretreatment technology. This could potentially extend the life of the granular activated carbon (GAC) utilized for removing contaminants from groundwater by lowering the mass of TCE entering the GAC beds.

2.0 BACKGROUND

Between 1998 and 2003, a 2.57% (by weight) aqueous solution of $KMnO_4$ was injected into the influent stream at SRTF in association with the use of greensand filters (GSFs) to remove dissolved and suspended iron and manganese from the process stream. $KMnO_4$ served to continuously regenerate the GSF media and was not originally intended to reduce the concentration of contaminants entering the treatment plant. Greensand is a processed material that includes nodular grains of the zeolite mineral glauconite that contains several metallic and semi-metallic elements (such as potassium, sodium, iron, aluminum, magnesium, and silicon). $KMnO_4$ regenerates greensand by being chemically reduced, and coating the surfaces of the greensand with manganese dioxide (MnO_2), a by-product of $KMnO_4$ reduction:

$$KMnO_4 + GSF\text{-}e^-_{(s)} + H_2O \rightarrow MnO_{2(s)} + GSF\text{-}e^-(OH)_{(s)} + KOH$$

Where:

$GSF\text{-}e^-$ = reduced green sand filter media
(s) indicates solid form

The MnO_2 then oxidizes dissolved ferrous iron. The injection of $KMnO_4$ was discontinued in January 2003 because it was no longer needed to remove ferrous iron from the process stream prior to GAC treatment. The concentrations of dissolved metals in the Storm Drain-5 (SD-5)

ITEM	REMARKS
	North influent stream decreased after the flanking extraction wells in the SD-5 North extraction fence (28EW0001 and 28EW0010) were taken out of operation These two wells were capturing groundwater containing low levels of volatile organic compounds (VOCs) and metals. $KMnO_4$ is frequently used *in situ* to oxidize contaminants (such as VOCs) present in aquifer formations. This process is commonly known as *In Situ* Chemical Oxidation (ISCO). With ISCO, relatively high $KMnO_4$ concentrations (thousands of parts per million) are used and the contact time between the contaminant and the KMnO4 is relatively long (weeks to months). The intent of the $KMnO_4$ injection test conducted at SRTF was to determine if injections of $KMnO_4$ into an existing pump and treat system could result in reduced operating costs and improved sustainability by reducing consumption of GAC. Initially, the MMR data warehouse was queried in order to determine if data from samples analyzed during the use of $KMnO_4$ injection for greensand filter regeneration might provide information on the effectiveness of this pretreatment method. The query was run for VOC data from any sample ports at the SRTF between the chemical injection point and the inlet to the GAC vessels. The query did not reveal any applicable data.
3.0	**TEST SETUP AND EXECUTION** The injection of $KMnO_4$ was performed utilizing the equipment at SRTF formerly used for this purpose. A process flow diagram indicating $KMnO_4$ injection location and sampling points is shown in Figure 1. A photograph of the $KMnO_4$ storage and injection system is shown in Figure 2. The injection system introduces chemical solution into the combined influent pipeline immediately upstream from a static mixer designed to homogenize the chemical solution and the process stream. The concentration of the $KMnO_4$ solution and the rate of injection of the solution into the process stream were chosen to match the parameters previously used for GSF media regeneration. For GSF media regeneration, a 2.57% (by weight) aqueous solution of $KMnO_4$ was injected at a rate of 1.12 gallons per hour (gph) per 1,000 gallons per minute (gpm) of process flow. For the current SRTF process flow rate of 770 gpm, this results in a $KMnO_4$ solution injection rate of 0.86 gph. At these flow rates, the concentration of $KMnO_4$ in the process water is approximately 0.5 milligrams per liter (mg/L). Prior to the start of the test, the chemical metering pump was set to 0.86 gph and the flow rate was confirmed by measuring the time to pump a specific volume of water out of the storage tank into the process piping. After the metering pump flow rate was set, a 2.57% $KMnO_4$ solution was prepared in the chemical holding tank and the injection test was started. Three injection events were conducted as part of the pilot testing. Each event lasted six hours. The pilot testing was conducted over three consecutive days. Between each injection event, the systems continued to operate without the injection of $KMnO_4$.

ITEM	REMARKS
	Table 1 contains the sampling plan for each injection event. All water samples were analyzed for VOCs using Environmental Protection Agency (EPA) Method 8260B. The laboratory analysis was performed by Analytics Environmental Laboratory, LLC in Portsmouth, New Hampshire. Immediately prior to the start of each injection event, baseline water samples for analysis were taken from the combined influent just upstream of the injection port (28PLT01005), the post-injection sample port downstream from the static mixer (28PLT01006), and the combined effluent from the three greensand filters (28PLT01010). Refer to Figure 1 for sampling port locations. Field parameters (temperature, specific conductivity, dissolved oxygen, pH, oxidation/reduction potential [ORP], and turbidity) were also measured at these sampling ports as well as the combined plant effluent downstream from the GAC vessels (28PLT01035). ORP measurements provide an indication of the presence of $KMnO_4$. The combined plant effluent port was not analyzed for VOCs since it is known that the GAC would remove most if not all of the dissolved VOCs. After baseline sampling was completed, injection of the $KMnO_4$ solution was started, and water samples and field parameters were taken 15 and 30 minutes, and 1, 2 , 4, and 6 hours after commencement of injection. This identical plan was executed on three consecutive days; 09-11 February 2011.
4.0	**RESULTS** Analytical data from each of the injection events are presented in Table 2. TCE concentrations at the combined influent sample port (28PLT01005), the post-injection sample port (28PLT01006), and the greensand filter effluent sampling port (28PLT01010) are presented graphically in Figures 3, 4, and 5. TCE concentrations in the combined influent remained relatively constant at the start of each of the three days of testing (Time = 0), varying from 19-20 micrograms per liter (µg/L). As expected, the TCE concentration at the post-injection sample port prior to commencement of chemical injection (Time = 0) was approximately equal to the combined influent concentration, varying from 17-20 µg/L on each of the three days of testing. After commencement of chemical injection on the first day of testing, the TCE concentration in the sample collected from the post-injection sample port after 15 minutes of injection remained relatively unchanged, but analyses of subsequent samples showed an approximately 50% decrease in TCE concentrations. Since the plumbing between the chemical mixing tank and the chemical injection port in the combined effluent piping had initially been tested with water and remained filled with clean water at the start of the first injection event, it took some period of time for the chemical solution to progress through the plumbing and into the chemical injection port in the combined effluent piping. This explains the higher TCE measurement in the 15 minute sample on the first day of testing. The $KMnO_4$ solution had not yet reached the injection port.

ITEM	REMARKS
	ORP readings increased substantially during chemical injection; from approximately 175 millivolts (mV) to approximately 520 mV at the post-injection port. This is to be expected due to the strongly oxidizing properties of $KMnO_4$. ORP values measured at the greensand filter effluent dropped substantially (to approximately 350-450 mV). This is likely due to the $KMnO_4$ being consumed by reaction with the greensand filter media and/or filtrate. See Figure 6 for a graph of ORP data. The notable reduction in TCE concentrations measured at the post-injection port for all three events seemed to indicate that the $KMnO_4$ was effectively destroying approximately 50% of the TCE entering the greensand filters. However, TCE concentrations measured at the effluent from the greensand filters was approximately equal to the combined plant influent concentration; varying from 19-21 µg/L. Similar results were observed on the second and third days of testing, with the exception of the then-filled chemical tubing resulting in the presence of $KMnO_4$ at the post-injection sample port, as evidenced by TCE results and ORP readings in the 15 minute samples. The reductions in TCE concentrations in the post-injection port samples coupled with results from the post-greensand sample port indicating virtually no change from influent concentrations were unexpected and seemingly contradictory. However, the results can be explained based on 1) laboratory holding time and, 2) reduction of $KMnO_4$ by the greensand filter media. <u>Laboratory Holding Time</u> All samples submitted to the laboratory for VOC analyses were submitted for standard turnaround time of 15 work days. Upon receipt of the samples at the laboratory the samples are stored under refrigeration at between 2-6 degrees Celsius (°C) until ready for analysis. Any unreacted $KMnO_4$ present in the sample would continue to be available to react with residual TCE in the sample up until the time of analysis. The laboratory reports indicate that the actual time between sample collection and laboratory analysis was approximately 13 days. By using first order degradation equations and published rate constants for reactions of $KMnO_4$ with TCE in aqueous solution, the time required to reach the concentration of TCE measured in the post-injection samples was calculated. The Arrhenius equation[1] was used to adjust the rates to the sample storage temperature of 4°C (see Appendix 1). This calculation predicts that at a $KMnO_4$ concentration of 0.5 mg/L, a TCE concentration of 20 µg/L, and a temperature of 4°C, it is expected that the time required to reach the observed post-injection port TCE concentration of 10 µg/L is 12.3 days; very close to the actual 13-day holding time. It is likely that if these samples had been analyzed very shortly after being taken, little or no change in the TCE concentration compared to the combined influent concentration would have occurred. Thus, the continued reaction of the TCE with the $KMnO_4$ during the sample holding time could explain the reduced concentration of TCE in the post-injection sampling port.

ITEM	REMARKS
	Reduction of $KMnO_4$ by the Greensand Filter Media It is likely that virtually all residual $KMnO_4$ present in the process stream was reduced by reaction with the greensand filter media. This is the mechanism formerly used to regenerate the greensand media when it was used for removal of metals. This likely left no dissolved $KMnO_4$ to react with TCE in the post-greensand sample vials. Consequently, the TCE concentration in the post-greensand samples indicated virtually no destruction of contaminants. These results together indicate that at a $KMnO_4$ concentration of approximately 0.5 mg/L, there is not adequate residence time in the system to result in any significant destruction of TCE. Using the rate calculations discussed above, the concentration of $KMnO_4$ required to produce a desired reduction in TCE concentration in the period of time available for reaction can be predicted. At the influent flow rate of 770 gpm, the time for a unit volume of water to flow through the headspace volume of the greensand filters is approximately 10 minutes. After passing through the greensand filter bed, the water then passes through the GAC beds. Any residual $KMnO_4$ and TCE is reacted or adsorbed in these beds, so 10 minutes can be used as the maximum period available for reactions to take place. At a $KMnO_4$ concentration of approximately 0.5 mg/L, this is not adequate residence time to result in any significant destruction of TCE. Based on these parameters, it is predicted that in order to reduce the TCE concentration from 20 µg/L to approximately 0.20 µg/L (the method detection limit for this compound[2]) an increase in the $KMnO_4$ concentration to approximately 2,250 mg/L (a 4,500-fold increase over that used in this test) would be required. This equates to an annual $KMnO_4$ consumption of approximately 3,600 tons. Bulk pricing (quantities over 50 tons) for $KMnO_4$ is approximately $2.50 per pound[3], resulting in an annual estimated cost of $18MM. Reducing TCE concentrations to the method detection limit is not necessarily required to have a significant effect on GAC consumption. Reducing TCE concentrations by 50% to approximately 10 µg/L would reduce GAC consumption significantly. However this reduction would still require a $KMnO_4$ concentration of approximately 325 mg/L, resulting in an annual $KMnO_4$ consumption of approximately 520 tons with an annual estimated cost of $2.6MM. The approximate annual cost of GAC use at SRTF is only $69,000 (six 20,000 lb loads at $11,500 per load). The concentration of $KMnO_4$ required could be reduced by increasing the reaction period. The SRTF has an influent equalization tank that could potentially be used to increase the reaction period if the chemical injection point were relocated to a location upstream of the influent tank. This additional volume would increase the reaction period to approximately 23 minutes. Under this scenario, the $KMnO_4$ concentration (and the annual cost) could be reduced by about half. However, even reducing the costs presented above by half would still result in costs that are far higher than use of GAC alone.

[2] The effluent discharge criteria for MMR treatment facilities is no detectable concentrations of contaminants of concern. Therefore, the method detection limit is assumed to be the effluent discharge criteria.

[3] Verbal estimate, Carus Corporation, 14 September 2011.

ITEM	REMARKS
5.0	**CONCLUSIONS AND RECOMMENDATIONS** Based on the information presented above, the use of $KMnO_4$ to reduce TCE concentrations is not likely to provide any cost benefit compared to the use of GAC for removal of all TCE from the process stream. Due to unfavorable reaction kinetics and the limited residence time in the treatment system, the amount of $KMnO_4$ required to produce any significant reduction in GAC consumption is very high, resulting in high operating costs in comparison to the use of GAC for removal of TCE. Due to these factors, it is recommended that no further investigation of this technology be performed.

SAMPLING LOCATIONS

DESCRIPTION	**LOC ID**
Combined influent	28PLT01005
Post-injection	28PLT01006
Post-greensand	28PLT01010
Post-GAC	28PLT01035

Objective

This appendix documents the calculations used to determine the degradation rate of trichloroethene (TCE) after post-injection sampling using permanganate (MnO_4^-) injection and to estimate the concentration of MnO_4^- required to lower TCE concentrations below the method detection limit in the amount of time available for reaction in the system.

Background

MnO_4^- is a commonly used chemical oxidant used to treat water contaminated with organic compounds such as TCE. MnO_4^- reacts with TCE breaking it down into intermediates including various organic intermediates, manganese dioxide, and MnO_4^- that further react with residual MnO_4^- for end products that can include carbon dioxide, manganese dioxide, and salts such as chloride (Siegrist 2011). The initial concentrations of both TCE and MnO_4^- control the rate of the reaction. The degradation of TCE by MnO_4 with respect to time is described using the following second-order kinetics equation (Siegrist 2011):

$$\dot{TCE}(t) = -k_2 TCE(t) MnO_4$$

where:

TCE = TCE concentration (mole per liter [mol/L])

t = time (seconds [s])

k_2 = second-order reaction rate constant (liters per mole-second [L/mol-s])

MnO_4^- = MnO_4^- concentration (mole per liter [mol/L])

The amount of time required for TCE to be oxidized by MnO_4^- is impacted by temperature changes. The reaction rate of MnO_4^- with TCE increases as temperature increases and can be calculated using the Arrhenius equation shown below:

$$k = A_f e^{\{-Ea/RT\}}$$

where:

k = second-order reaction rate constant (liters per mole-second [L/mol-s])

A_f = Arrhenius frequency factor

E_a = activation energy of the reaction (kilojoules per mole [kJ/mol)

R = gas constant (8.314 joules per temperature Kelvin-mole [J/K-mol)

T = temperature (Kelvin [K])

TCE Degradation Calculations

Integration of the second-order equation (Siegrist 2011) assuming exponential growth results in the following equation and can be used to predict the concentration of TCE as time increases:

$$TCE(t) = TCE_0 e^{-k_2 MnO_4 t}$$

Samples were stored under refrigeration at the laboratory between 2 to 6 degrees Celsius (°C) prior to analysis. For purposes of this evaluation, samples were assumed to be stored at 4°C prior to analysis. Reaction rate constants presented in Figure 3.3 of the *In Situ Chemical Oxidation for Groundwater Remediation* book (Borden 2011) were used to interpolate and determine a rate constant of 0.1538 L/mol-s for the reaction of MnO_4^- with TCE. The calculated rate constant and second-order integration equation were used to determine the amount of time required

to reach the post-injection concentration of TCE measured at the laboratory. Using the integration of the second-order equation previously presented to solve for time, the estimated time to reach the post-injection TCE concentration (10 micrograms per liter [µg/L]) was estimated at 12.3 days:

$t = (ln[TCE/TCE_0])/(-k_2MnO_4)$
$t = (ln[7.65\ E\text{-}08\ mol/L/1.52\ E\text{-}07\ mol/L])/(-0.1538\ L/mol\text{-}s*4.20\ E\text{-}06\ mol/L)$
$t = (1{,}062{,}898\ s)*(1.16\ E\text{-}05\ days/s)$
$t = 12.3\ days$

Potassium Permanganate ($KMnO_4$) Calculations

Using the same rate calculations discussed above, the concentration of $KMnO_4$ required to produce a desired reduction in TCE concentration over a certain period of time can be predicted. This is the method utilized in the Project Note to estimate the amounts of $KMnO_4$ required to reduce TCE concentrations to desired levels in the amount of time available for reaction in the treatment system.

ITEM	REMARKS
1.0	**INTRODUCTION** This project note summarizes the Chemical Spill-10 (CS-10) 2010/2011 Biennial Data Presentation which included data collected for the CS-10 System Performance and Ecological Impact Monitoring (SPEIM) program and the CS-10 Long Term Monitoring (LTM) program between October 2010 and April 2011. The data presented included results from the following: • Biennial/annual/semiannual groundwater sampling event; • Semiannual extraction well sampling event; • Monthly sampling of treatment plant ports; • Flow testing at 00EW0001 and 03EW2110 associated with optimization evaluations; • Johns Pond surface water sampling; • Three quarterly in-situ chemical oxidation (ISCO) sampling events; and • CS-10 In-Plume data gap investigation. These data were presented during the 29 September 2011 Technical Update meeting. The handouts for the presentation included 10 figures and presentation text slides. The handout is included as **Attachment A**.
2.0	**BACKGROUND** The contaminants of concern (COCs) for the CS-10 plume are trichloroethene (TCE) and tetrachloroethene (PCE). Three treatment systems were designed to remediate the CS-10 plume: (1) the CS-10 Sandwich Road extraction, treatment, and reinjection (ETR) system; (2) the CS-10 In-Plume extraction, treatment, and infiltration (ETI) system; and (3) the Northern Lobe (i.e., the northernmost leading edge lobe) extraction well.

ITEM	REMARKS
	Analytical data for the CS-10 plume have been collected through the SPEIM program since 1999 when the first remedial system went on-line. The SPEIM program was developed to monitor plume changes and to ensure the effective operation of the groundwater remediation systems and identify potential optimization opportunities; monitoring networks are also evaluated and optimized through the SPEIM program. Monitoring for the two CS-10 leading edge lobes that do not have active remediation (North Central Lobe and Southern Lobe) and monitoring on the eastern side of Johns Pond is completed under the CS-10 LTM program. The current approved CS-10 SPEIM/LTM network, including the analytical scope and methods, is presented in the *Comprehensive Long Term Monitoring Plan (CLTMP)*, which is available on-line at www.mmr.org under Plans and Protocols. During this reporting period sampling activities also included flow testing of extraction wells 03EW2110 and 00EW0001 to evaluate potential optimized operating conditions; rotosonic and direct push drilling for an ongoing data gap investigation that will provide information needed to optimize the CS-10 In-Plume and Sandwich Road remedial systems and to update the CS-10 conceptual site model (CSM), and supplemental ISCO pilot test sampling to further evaluate the migration and persistence of the oxidant and impacts from the injection which was conducted in November 2007.
3.0	**RESULTS** Analytical results for TCE and PCE and general concentration trends were presented for selected sampling locations in the CS-10 In-Plume, Southern Trench, Sandwich Road, Northern Lobe, and other leading edge areas. An overview of remedial system operations during the reporting period was presented by providing extraction well and treatment plant influent concentrations, TCE and PCE mass removal calculations, extraction well operational rates, number of carbon exchanges, and electrical usage with estimates of associated air emissions. Results from the ongoing data gap investigation (consisting of direct push and rotosonic drilling), optimization flow testing at 00EW0001 and 03EW2110, and ISCO pilot test sampling results were also presented (**Attachment A**). Note that all the analytical data collected in 2010 for the CS-10 SPEIM and LTM programs were included in the *Chemical Spill-10 2010 Summary Letter Report* (AFCEE 2011), and all the analytical data collected in 2011 will be included in the *Chemical Spill-10 2011 Summary Letter Report*, which is scheduled for submittal in March 2012.
4.0	**CONCLUSIONS** **CS-10 In-Plume** • No Maximum Contaminant Level (MCL) exceedances have been detected in monitoring wells located between the source area and the northernmost extent (trailing edge) of the CS-10 plume boundary since 2005. However, a 10 to 20 foot thick zone of MCL exceedances of TCE was observed in groundwater screening results collected from two borings located along the trailing edge of the CS-10 plume: direct push boring 03DP1066 (12.1 micrograms per liter [µg/L]) and

ITEM	REMARKS

rotosonic boring 03MW1064A (5.6 and 25 µg/L). In addition, a 10 foot thick zone of MCL exceedances of PCE was detected in groundwater screening results collected from one rotosonic boring located upgradient of the trailing edge, 03MW1089A (12.3 µg/L at 33.5 feet mean sea level [ft msl]). After the data gap investigation is completed the CS-10 plume boundary will be revised to delineate the trailing edge of the CS-10 plume slightly north of rotosonic boring 03MW1089A.

- Several high TCE concentration lobes upgradient of 03EW2102 and higher TCE concentration areas upgradient of extraction wells 03EW2103, 03EW2104, and 03EW2105 have been identified during the data gap investigation. MCL exceedances have also been detected outside the current CS-10 plume boundary.
- The maximum TCE concentrations in the CS-10 plume are located upgradient of CS-10 In-Plume extraction well 03EW2102 (3,880 µg/L in rotosonic boring 03MW1069A). TCE MCL exceedances were observed over a 150 ft thick zone in this area with maximum concentrations between -60 and -80 ft msl. TCE influent concentrations at 03EW2102 have remained consistently high since system startup (86 µg/L in 2010) (slide 5 in **Attachment A**).
- Elevated TCE concentrations (325 µg/L in rotosonic boring 03MW1075A) and a 120 ft thick zone of contamination were detected upgradient of 03EW2104 during the data gap investigation; contamination in several borings completed in this area extended to bedrock.
- The maximum TCE concentration detected upgradient of 03EW2105 was 803 µg/L in direct push boring 03DP1110 and MCL exceedances extended over a 60 ft thick zone (between -14.5 and -74.5 ft msl). Maximum PCE concentrations in the CS-10 plume are detected upgradient of 03EW2105 at monitoring well 03MW0109B (screened from -28 to -33 ft msl); PCE concentrations at this well decreased from 123 µg/L in 2010 to 85 µg/L in 2011.
- Extraction well 03EW2106 was taken out of operation on 24 February 2010 (AFCEE 2010). The TCE concentrations at 03EW2106 and in the area of 03EW2106 continue to support the shutdown of this well; any remaining contamination in this area is located within the capture zones of 03EW2103 or 03EW2105.
- The draft 2011 TCE plume shell, which includes all the data gap investigation results, has approximately 103 percent more mass and 29 percent more volume than the previous (January 2008) TCE plume shell and the maximum TCE concentration in the draft 2011 plume shell is 3,880 µg/L compared to 450 µg/L in the 2008 version.
- Based on preliminary transport modeling results using the draft 2011 TCE plume shell, the CS-10 In-Plume system is still meeting the system design expectations of plume capture, and the newly characterized TCE contamination identified to the east of the current plume boundary is located within the Sandwich Road system capture zone.
- The CS-10 IP system removed 116 pounds (lbs) of TCE and 8 lbs of PCE between January and June 2011, and 4,067 lbs of TCE and 507 lbs of PCE since system startup in 1999. Approximately 50 percent of this mass was removed by one extraction well, 03EW2102.

ITEM	REMARKS

ISCO Pilot Test

- An ISCO injection (using sodium permanganate) was completed in November 2007 in an area located north and hydraulically upgradient of extraction well 03EW2109 as part of a pilot test. The presence of sodium permanganate was still observed at two pilot test monitoring locations (03MW1024D and 03MW1036A) in June 2010, over 2.5 years after the injection. TCE concentrations in most wells located within the pilot test site have decreased since the ISCO injection in November 2007 and TCE concentrations in two downgradient wells have also decreased. TCE concentrations in some pilot test wells have returned to pre-injection (i.e., baseline) concentrations, which is consistent with high TCE concentrations detected upgradient of the ISCO pilot test site migrating back into the area.

CS-10 Southern Trench

- TCE concentrations in monitoring wells located downgradient (i.e., south) of 03EW2111 have generally decreased and based on observed increases in TCE concentrations in monitoring wells located south of the base boundary, contamination appears to have migrated downgradient of the base boundary toward 03EW2112 (slide 23 in **Attachment A**).
- Southern trench extraction well 03EW2112 began operation on 19 February 2009. Based on groundwater monitoring results and influent concentrations at 03EW2112, the leading edge of the southern trench lobe of the CS-10 plume had not yet reached 03EW2112 and 03EW2112 was temporarily taken out of operation on 17 April 2009.
- After a data gap investigation which included increased sampling of monitoring wells in the southern trench area, the completion of two rotosonic borings (03MW1058A and 03MW1059A), installation of six monitoring wells (03MW1058A,B,C and 03MW1059A,B,C), two flow tests and groundwater flow and transport modeling; a recommendation to operate 03EW2112 at the more efficient flow rate of 100 gallons per minute (gpm) with a packered configuration (blocking off the bottom 40 feet of the well screen with a packer) was presented at the December 2010 Technical Update meeting. Extraction well 03EW2112 has been operating at this optimized scenario since January 2011 and TCE influent concentrations increased from below the reporting limit to 2 µg/L in 2011.

CS-10 Sandwich Road

- TCE influent concentrations exceeded the MCL in two operational Sandwich Road system extraction wells: 03EW2173 (21 µg/L) and 03EW2174 (7.5 µg/L).
- Two off-line extraction wells (03EW2176 and 03EW2177) were turned back on in 2011 after TCE MCL exceedances were observed in 03EW2177 (during sampling of offline well). A data gap investigation is ongoing to determine the extent of contamination in this area and 03EW2176 and 03EW2177 have been turned back on and are operating at the interim flow rates of 75 and 50 gpm, respectively, to improve the hydraulic capture of the Sandwich Road ETR system. Once the uncertainty of the extent of contamination in this

ITEM	REMARKS
	area has been addressed, optimization of the Sandwich Road system will be completed using the revised TCE plume shell and the recalibrated groundwater flow model as part of the CS-10 In-Plume optimization modeling effort. • TCE concentrations in trailing edge well 03MP0091A decreased below the MCL for the first time since sampling began in 1998 (from 12 µg/L in 2009 to 2.8 µg/L in 2011); a historical maximum TCE concentration of 1,500 µg/L was observed at this well in 2001. • The CS-10 Sandwich Road system removed approximately 8 lbs of TCE and 0.4 lbs of PCE between January and June 2011, and 1,019 lbs of TCE and 23 lbs of PCE since system startup in 1999. **CS-10 Leading Edge** • Increases in TCE influent concentrations at the Northern Lobe extraction well (00EW0001) are consistent with increasing TCE concentrations in upgradient wells. Based on monitoring results and modeling predictions the extraction well is containing the plume and operating as designed. Flow testing at 00EW0001 is ongoing to determine if the flow rate could be optimized to improve performance; the well is currently operating at 225 gpm. Northern Lobe extraction well (00EW0001) removed approximately 26.6 lbs of TCE between January and June 2011 and has removed 300.3 lbs of TCE since system startup in 2000. • Concentrations in the North Central Lobe and Southern Lobe are generally consistent with previous results and with the conceptual site model for these two lobes. • Analytical results collected on the east side of Johns Pond are consistent with the conceptual site model and indicate that the Mashpee Village Public Water Supply well and sentry wells are not impacted by the CS-10 plume. TCE concentrations at one well located on the east side of Johns Pond (00MW0584A), where low-level MCL exceedances (5.1 µg/L) were observed in 2003, increased above the MCL to 6.2 µg/L in 2011. This monitoring well is screened deep in the aquifer (-238 to -243 ft msl), just above bedrock and contamination at this location will not have an impact on the Mashpee Water Supply well (AFCEE 2005). TCE concentrations at other monitoring wells in this area were consistent with previous sampling events.
5.0	**RECOMMENDATIONS/PATH FORWARD** • The In-Plume data gap investigation is ongoing; recommend revising the CS-10 plume boundary and finalizing the TCE plume shell after the data gap investigation is completed. Data collected during this data gap investigation will also be used to recalibrate the groundwater flow model and to complete transport modeling to evaluate potential optimization scenarios for the CS-10 In-Plume and Sandwich Road systems.

ITEM	REMARKS
	• Recommend operating Sandwich Road extraction wells 03EW2176 and 03EW2177 at interim flow rates (75 and 50 gpm, respectively) until the plume extent in this area is determined and optimization modeling of the CS-10 In-Plume and Sandwich Road systems is completed. • Based on flow testing results at 00EW0001, it is recommended that 00EW0001 continue operating at the higher flow rate of 225 gpm until TCE influent concentrations continually decrease. • Recommend continued groundwater sampling at selected ISCO pilot test wells to further evaluate the concentration trends for TCE, selected metals, and total dissolved solids. • Recommend CS-10 SPEIM/LTM monitoring network revisions including: (i) reducing the sampling frequency of southern trench area wells from semiannual to annual; and (ii) increasing the sampling frequency of 00MW0584A (located on the east side of Johns Pond) from biennial to annual. A summary of the CS-10 SPEIM/LTM monitoring network revisions is included in **Attachment B**. The locations of the wells are shown on the figures in **Attachment A**.
6.0	**COMMENTS/ACTION ITEMS** A follow-up with the regulatory agencies was conducted during the 17 November 2011 Technical Update meeting. No additional comments regarding the results, conclusions, and recommendations presented during the 2010/2011 biennial data presentation were received or action items identified.

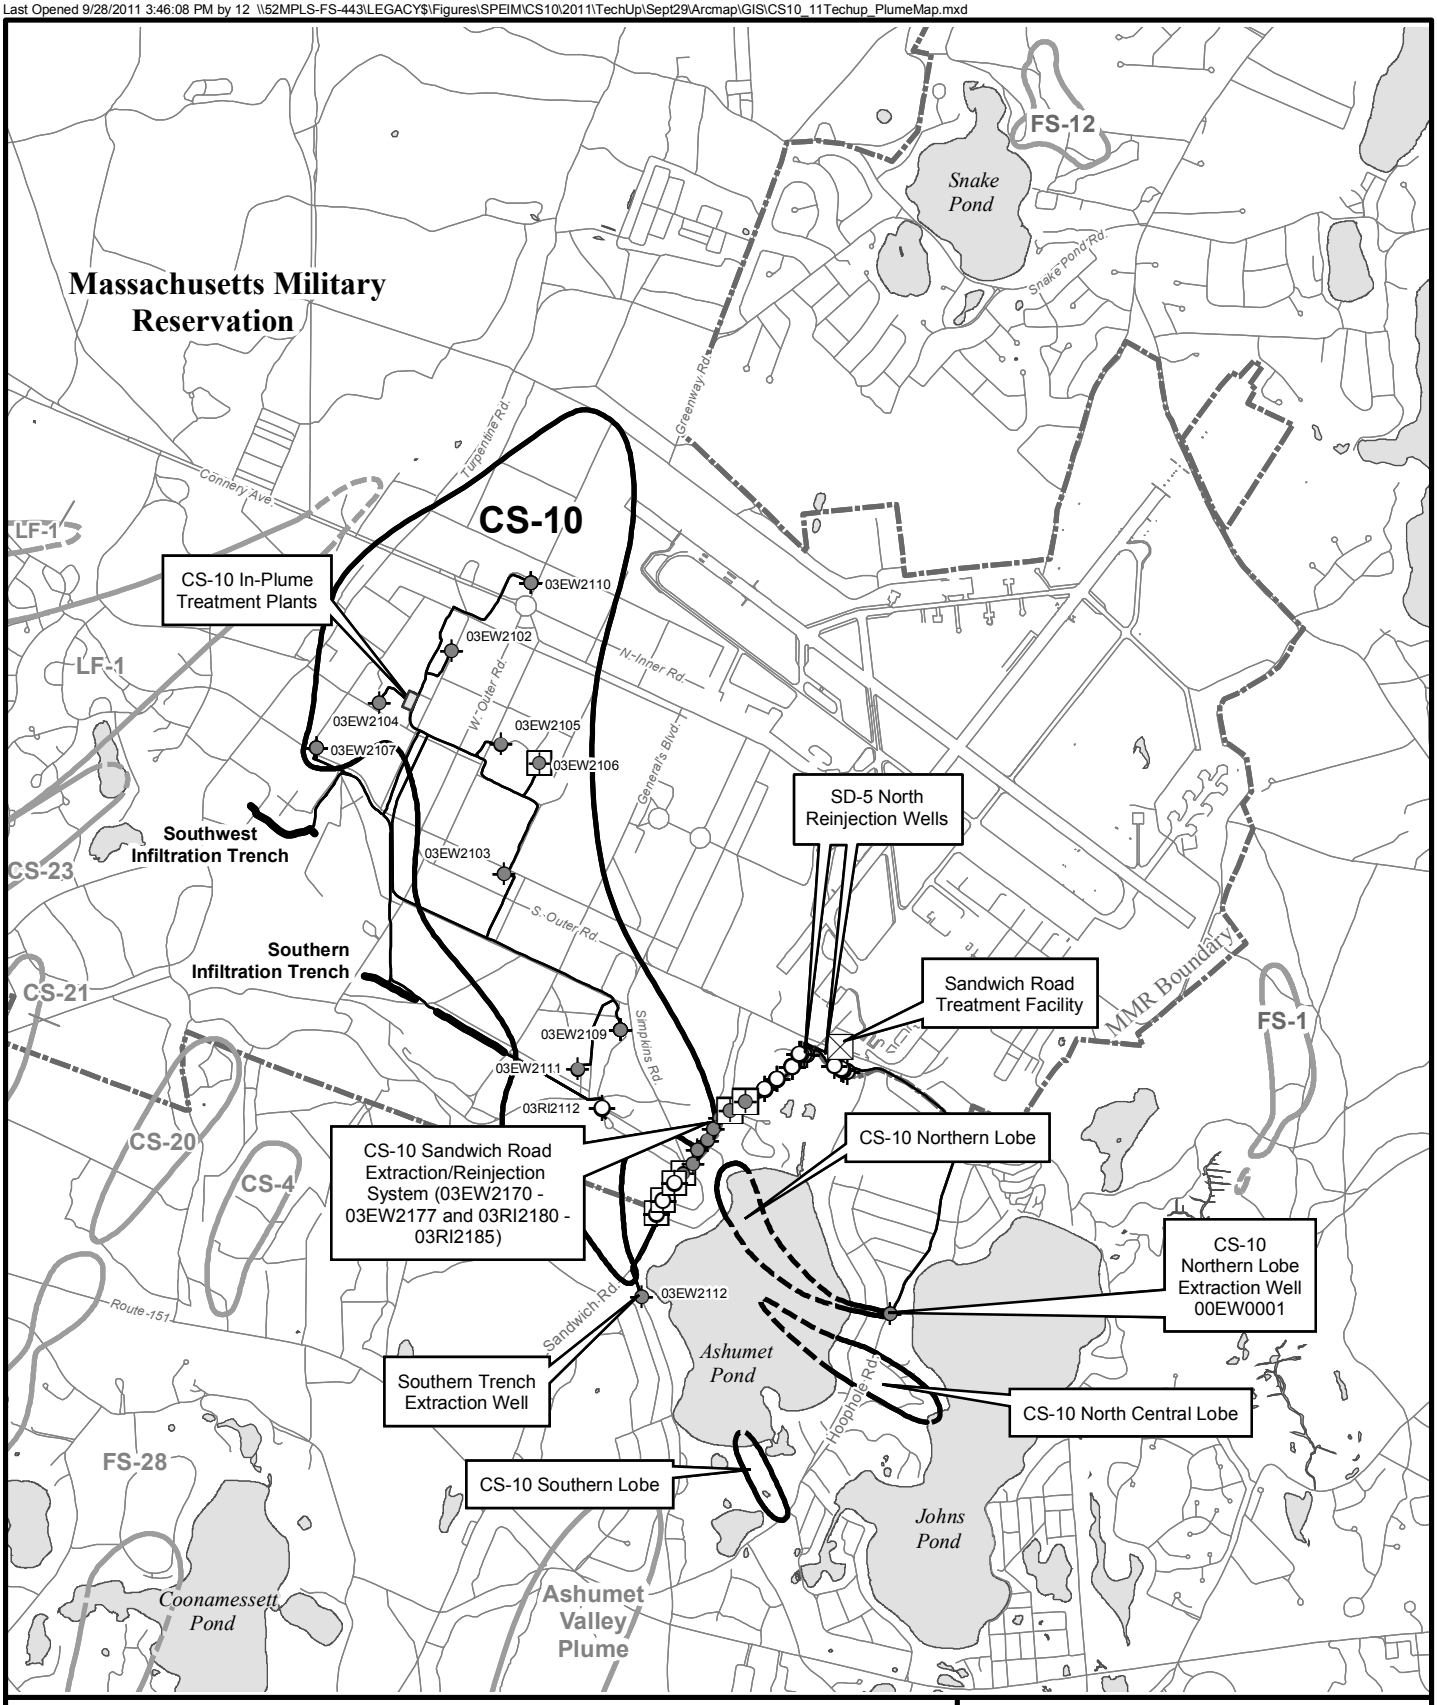
29 September 2011 Technical Update Meeting

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting



Sampling Dates: October 2010 through April 2011

Sampling Events:

- Biennial/Annual/Semiannual sampling event
- Semiannual extraction well sampling
- Flow testing at 00EW0001 and 03EW2110
- Johns Pond surface water sampling
- Three Quarterly ISCO sampling events (7 locations)
- Data gap investigation

Deviations:

- Sampling event took seven months to complete; field team was supporting data gap investigation.
- Reduced 2011 semiannual sampling event (August 2011) to extraction wells only.
- Access to wells 03MW2625A,B was denied by property owner.

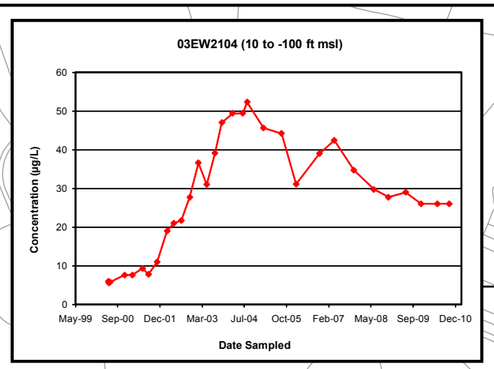
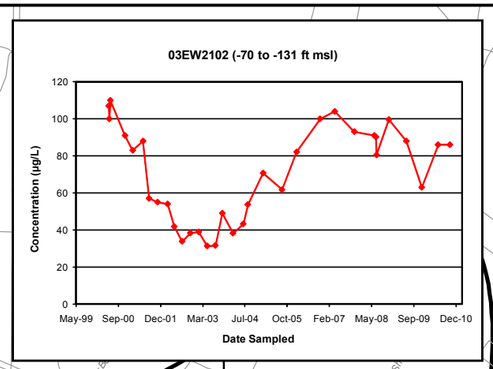
CS-10 In-Plume Results:



Extraction Wells



- TCE influent concentrations exceeded the MCL in six of the nine In-Plume extraction wells; maximum TCE influent concentration of 86 µg/L was detected at 03EW2102 (design flow rate of 460 gpm).
- TCE concentrations were relatively consistent with previous sampling event; increasing trends are observed at 03EW2109 and 03EW2111.
- 03EW2106 was taken out of operation in February 2010; TCE concentrations were 1.1 and 1.2 µg/L in 2010.
- PCE was detected above the RL in 3 In-Plume extraction wells: 03EW2103 (2.3 µg/L), 03EW2105 (5.1 µg/L), and 03EW2110 (2.7 µg/L).
- In-Plume extraction wells operated between 91 and 97 percent of their design flow rates between January and June 2011.

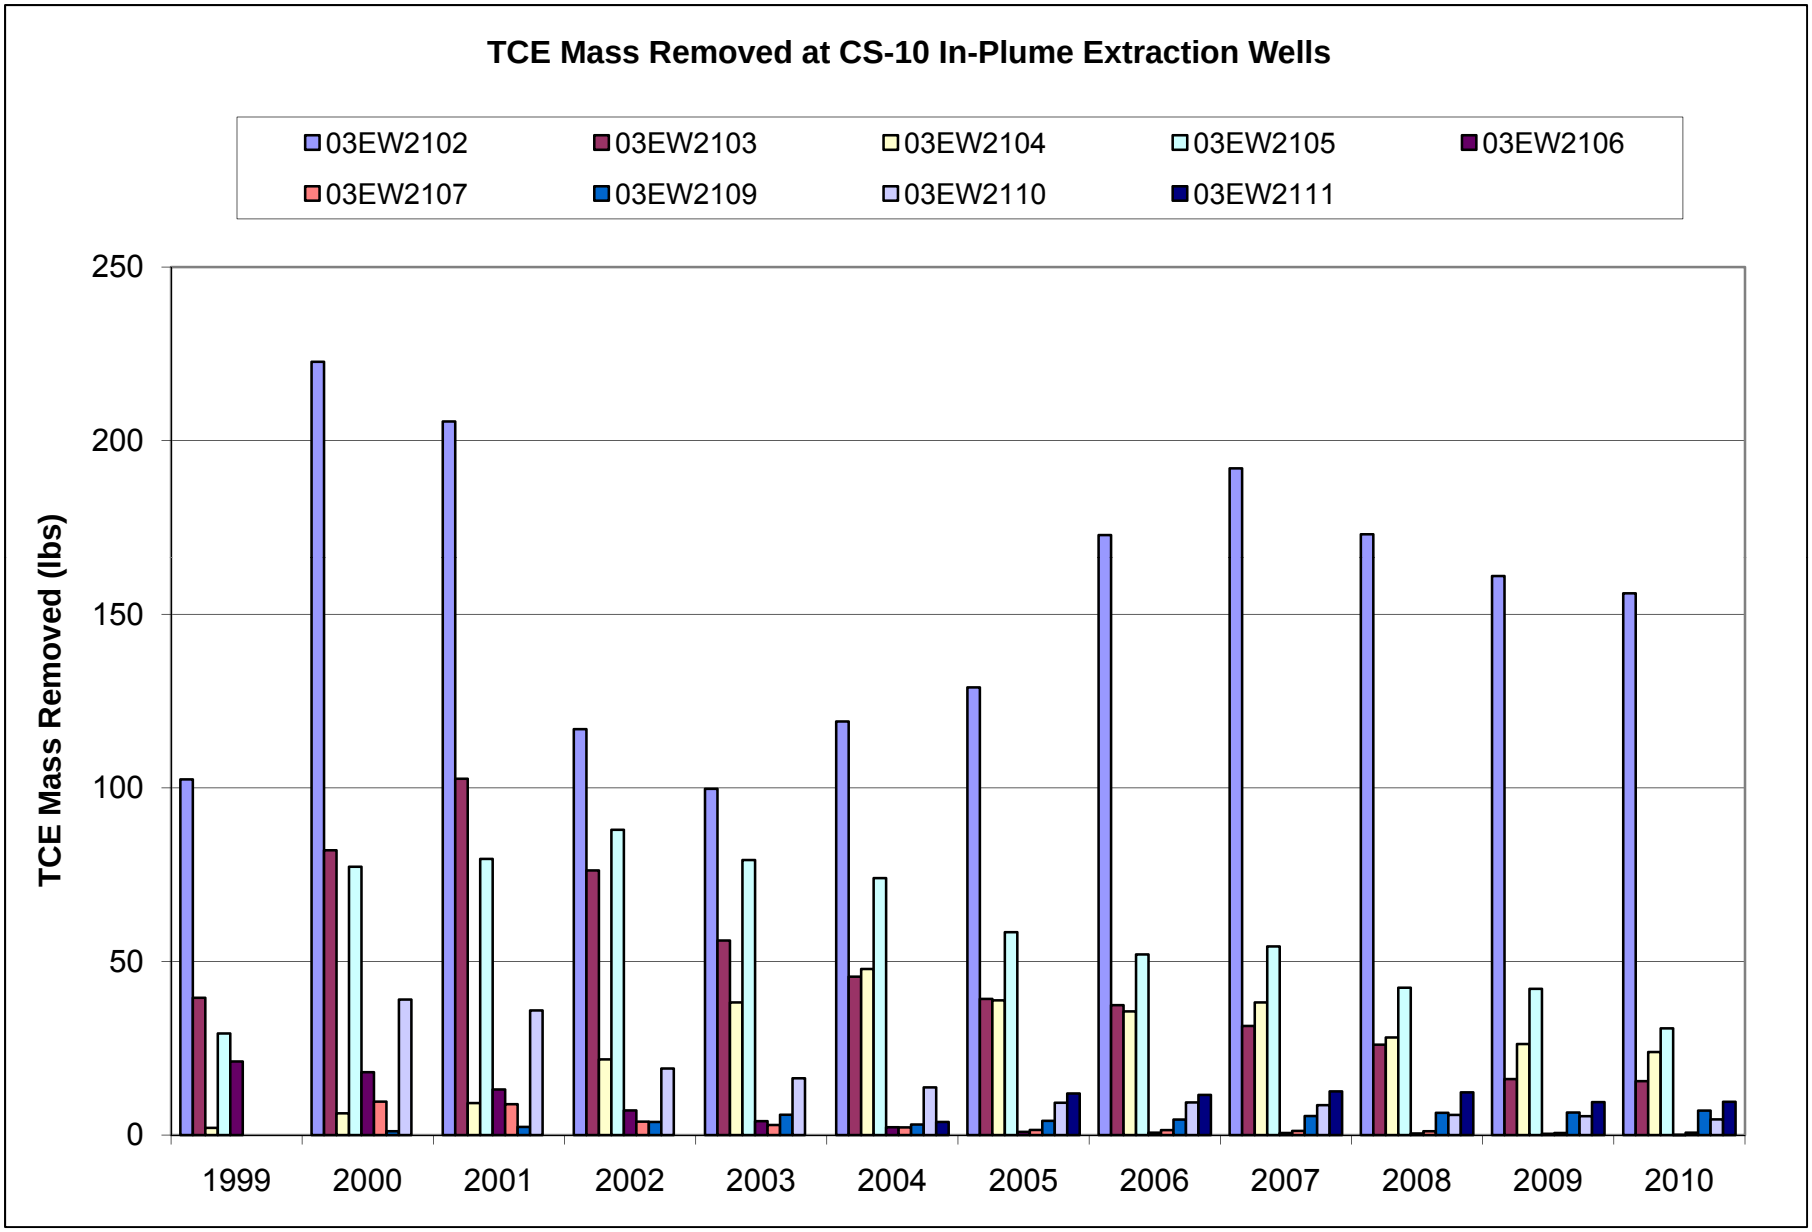
29 September 2011 Technical Update Meeting

CS-10 In-Plume Results:

Plant (January to June 2011)

– TCE influent concentrations at the CS-10 In-Plume plants ranged from



11.0 to 13.0 µg/L in Plant A (519 gpm) 41.0 to 59.7 µg/L in Plant B (489 gpm)

11.0 to 13.0 µg/L in Plant C (504 gpm) 34.0 to 48.6 µg/L in Plant D (515 gpm)

- PCE influent concentrations did not exceed the MCL in any of the CS-10 In-Plume plants (ranged from BRL to 2.69 µg/L).

– CS-10 IP system removed 116 lbs of TCE and 8 lbs of PCE between January and June 2011, and 4,067 lbs of TCE and 507 lbs of PCE since system startup.

– Approximately 530 million gallons of groundwater were treated by the CS-10 IP system and 8 carbon exchanges were completed from January to June 2011.

Notes:

1) The estimated air emissions presented in this table are based on the assumption that until 4/30/2009, the power used to operate the MMR remedial systems was provided by the Mirant Canal Station power plant in Sandwich, MA. This power plant primarily produced electricity generated by the combustion of fuel oil and has been off-line since 5/1/2009. Starting on 5/1/2009, air emissions are based on electricity generated by the average mix of power sources in Massachusetts. Air emissions were calculated using MMR utility data from AFCEE's Metrix 4 Utility Accounting Software (http://www.abraxasenergy.com/metrix4.php) and emission factors obtained from the following websites:
http://www.csgnetwork.com/elecpowerpolcalc.html
http://www.metrixcentral.com/EmissionsCalculator/Emissions%20Factors%202004.pdf
2) Option to purchase electricity from renewable sources is not available for CS-10 In Plume accounts.
3) Emissions offset by operation of AFCEE-owned wind turbine beginning on 12/2/2009.

Key:
COC = contaminant of concern
CO_2 = carbon dioxide reported in tons
CS-10 = Chemical Spill-10
MMR = Massachusetts Military Reservation
MWh = megawatt hours
NO_x = nitrogen oxides reported in pounds
PM-10 = particulate matter with a diameter of 10 micrometers or less reported in pounds
SO_2 = sulfur dioxide reported in pounds
VOCs = volatile organic compounds reported in pounds

CS-10 IN-PLUME AREA COC DETECTIONS

AFCEE - Massachusetts Military Reservation

29 September 2011 Technical Update Meeting

CH2MHILL

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

CS-10 In-Plume Results:

Maximum Concentrations:

- Maximum TCE concentration of 506 µg/L (2011) in 03IJW001A (571 µg/L in 2010).
- Maximum PCE concentration of 123 µg/L (2010) in 03MW0109B (159 µg/L in 2008).
- Maximum TCE concentration detected during the In-Plume data gap investigation was 3,880 µg/L in boring 03MW1069A (May 2010).
- Maximum PCE concentration detected during the In-Plume data gap investigation was 51 µg/L in boring 03DP1082 (January 2010).

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

CS-10 In-Plume Results:

Source Area

- No MCL exceedances had been detected between the source area and the northernmost extent (trailing edge) of the CS-10 plume boundary since 2005.
- In 2010, PCE concentrations at 03MW0020 increased from 2.2 (Nov 2009) to 12 µg/L (Dec 2010).
- MCL exceedances for PCE were observed in groundwater screening results collected from 03MW1089A (12.3 µg/L at 33.5 ft msl in July 2011).
- TCE has not been detected above the reporting limit of 1 µg/L in any source area or trailing edge well since 2004.
- MCL exceedances of TCE were observed in groundwater screening results collected from 03DP1066 (12.1 µg/L at -55.5 ft msl in Feb 2009) and 03MW1064A (5.6 and 25 µg/L at -50.5 and -60.5 ft msl, respectively in Feb 2010).

CS-10 SPEIM/LTM
2009 Annual Data Presentation
29 September 2011 Technical Update Meeting

CS-10 In-Plume Results:

03EW2102 (screened from -70 to -131 ft msl)

- Maximum TCE concentration detected during the In-Plume investigation was 3,880 µg/L (-60.5 ft msl) in boring 03MW1069A; MCL exceedances ranged from 6.4 to 3,880 µg/L between -10.5 and -150.5 ft msl (150 ft thick zone).
- Maximum TCE concentration detected in biennial monitoring network was 81 µg/L in 03MW0031 (180 µg/L in 2009); screened from -11.45 to -16.45 ft msl.
- Several distinct high concentration lobes were detected upgradient of 03EW2102; maximum TCE concentrations of 3,880, 1,700, and 960 µg/L in three lobes were detected at consistent elevations (between -60 and -80 ft msl).

CS-10 SPEIM/LTM
2009 Annual Data Presentation
29 September 2011 Technical Update Meeting

CS-10 In-Plume Results:

03EW2104 (screened from 10 to -100 ft msl)

- Maximum upgradient TCE concentration detected in biennial monitoring network was 6.8 µg/L in 03MW0035 (16 µg/L in 2009); screened from -12 to -17 ft msl.
- TCE concentrations in well located adjacent to 03EW2104 (03MW2150A) decreased from 230 to 108 µg/L; screened from -64 to -69 ft msl.
- Maximum TCE concentration detected during the In-Plume investigation was 325 µg/L (-106.5 ft msl) in boring 03MW1075A; MCL exceedances ranged from 5.3 to 325 µg/L between -6.5 and -126.5 ft msl (120 ft thick zone).
- Much higher TCE concentrations and a thick zone of contamination detected upgradient of 03EW2104 during data gap investigation, contamination in several borings extended to bedrock.

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

CS-10 In-Plume Results:

<u>03EW2105 (screened from 2 to -40 ft msl)</u>

- Maximum TCE concentration detected in biennial monitoring network, upgradient of 03EW2105 was 252 µg/L in 03MW2106A (increased from 15.2 µg/L in 2008); screened from -97 to -107 ft msl.
- Maximum TCE concentration detected during the In-Plume investigation was 803 µg/L in 03DP1110 (-24.5 ft msl); MCL exceedances ranged from 9.1 to 803 µg/L between -14.5 and -74.5 ft msl (bottom of boring).
- Maximum PCE concentrations are detected upgradient of 03EW2105:

  85 µg/L in well 03MW0109B and 52 µg/L in boring 03DP1082.
- Notable changes in TCE concentrations :

  03MW0046 (40 µg/L to BRL), 03MW2111B (710 to 456 µg/L),

  03MW0109B (132 to 61 µg/L), 03MW2106A (15.2 to 252 µg/L).

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

CS-10 In-Plume Results:

<u>03EW2106 (screened from 18 to -57 ft msl)</u>

- 03EW2106 was taken out of operation in February 2010.
- TCE concentrations at off-line well 03EW2106 were 1.1 and 1.2 µg/L in 2010.
- TCE concentrations in monitoring wells located upgradient and downgradient of 03EW2106 generally decreased.
- Notable changes in TCE concentrations :

  Upgradient Wells: 03MW0033 (4.5 µg/L to BRL) and 03MW0112B (14 to 4.2 µg/L)

  Downgradient Well: 03MW2153A (13 to 5 µg/L)

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

CS-10 In-Plume Results:

<u>03EW2109 and ISCO Pilot Test Site</u>

- Presence of permanganate was still observed at two locations (03MW1024D and 03MW1036A) through June 2010, over 2.5 years after the injection.

- TCE concentrations in wells located at the ISCO site decreased since the ISCO injection in Nov 07 at: 03MW1024A (590 to 39 µg/L), 03MW1024E (206 to 41 µg/L), and 03MW1036A (148 to 20 µg/L) and increased or returned to background concentrations at : 03MW1024C (112 to 392 µg/L) and 03MW1024D (450 to 313 µg/L).

- High TCE concentrations continue to be detected upgradient of the ISCO site: 03IJW001A (204 to 506 µg/L), 03DP0039C (120 to 111 µg/L), and 03MW0096 (38.9 to 60 µg/L).

- TCE concentrations in two wells located downgradient of the ISCO site and upgradient of 03EW2109 decreased since the ISCO injection in Nov 07 : 03DP0033A (229 to 106 µg/L) and 03MW2610A (204 to 83 µg/L).

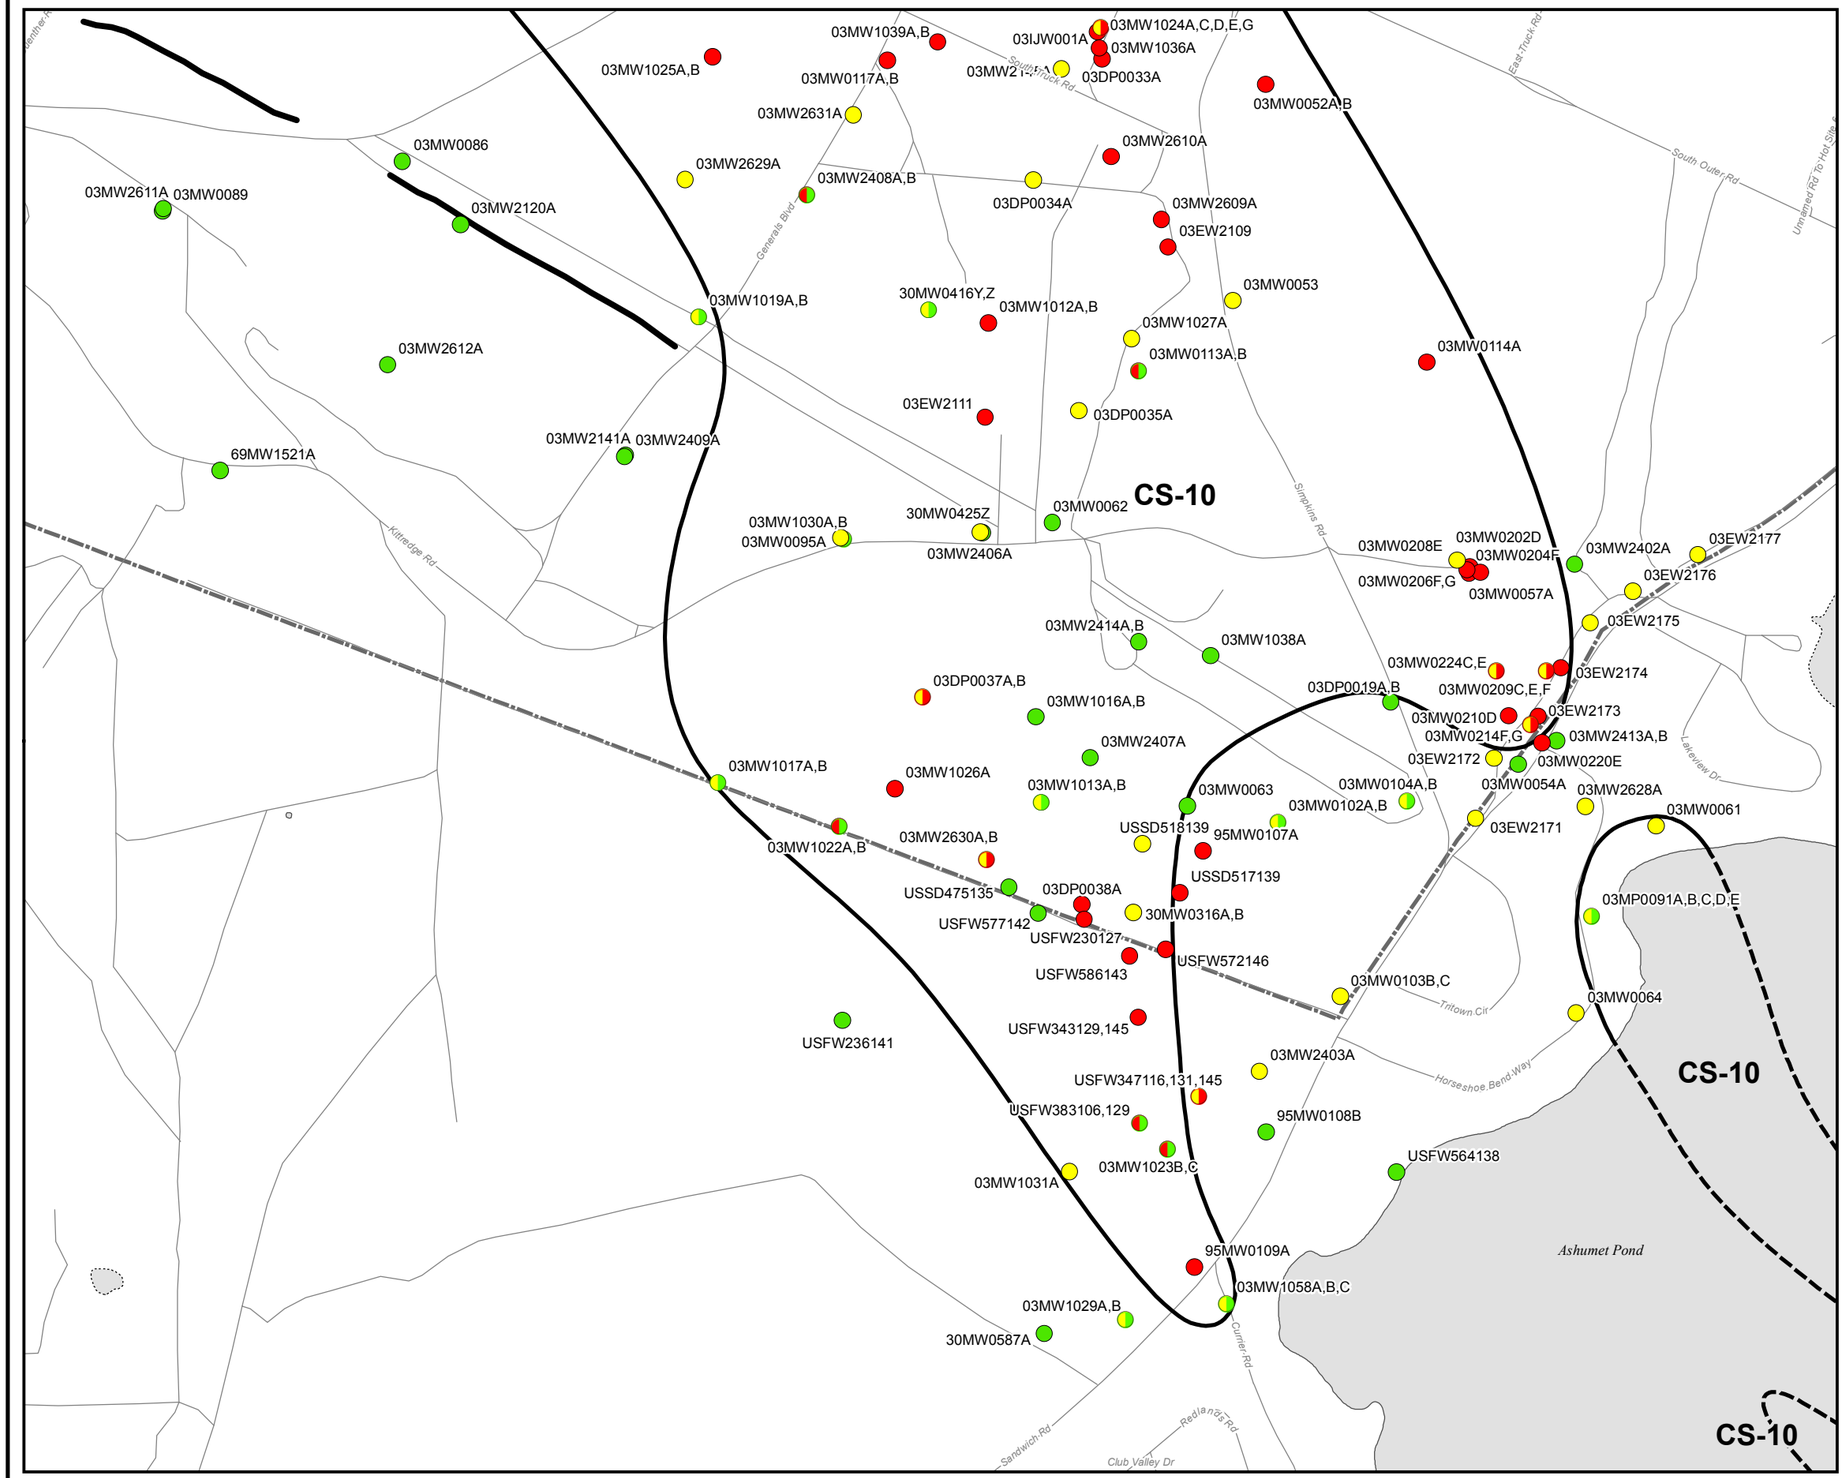
CS-10 In-Plume Results:

Draft 2011 CS-10 TCE Plume Shell Revision Summary

Statistics



- Approximately 103% more mass and 29% more volume than the January 2008 plume shell.
- Maximum TCE concentration increase from 450 to 3,880 µg/L.

TCE Distribution Changes

- New plume shell will extend 1,000 feet further east, 1,500 feet further north, 1,000 feet further west , and 1,000 feet further south (in the vicinity of 03EW2107).

TCE Concentration Changes

- New plume shell will show separation immediately south of 03EW2111.
- Lower TCE concentrations north of 03EW2111 and 03EW2109.
- Higher TCE concentrations near 03EW2102, 03EW2104, and north of 03EW2103, 03EW2110.

29 September 2011 Technical Update Meeting

CS-10 Southern Trench Results:

TCE concentrations upgradient of 03EW2111 fluctuated.

- Notable decreases in TCE concentrations: 03MW0117B (36 to 27 µg/L, maximum of 132 in 2006), 03MW1018B (99 to 32 µg/L, maximum of 168 in 2008), 03MW1020B (140 to 54 µg/L, maximum of 179 in 2007), 03MW2110A (6.2 to 1.1 µg/L, maximum of 340 in 2001), and 03MW2631A (74 to 4.6 µg/L, maximum of 167 in 2006).

- Notable increases in TCE concentrations: 03MW1020A (4.1 to 54 µg/L), 03MW1012A (6.6 to 18 µg/L), and 03MW2408B (ND to 9.5 µg/L).

- TCE influent concentrations at 03EW2111 increased from 4.7 to 6.3 µg/L.

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

CS-10 Southern Trench Results:

TCE concentrations between 03EW2111 and the Base Boundary generally decreased

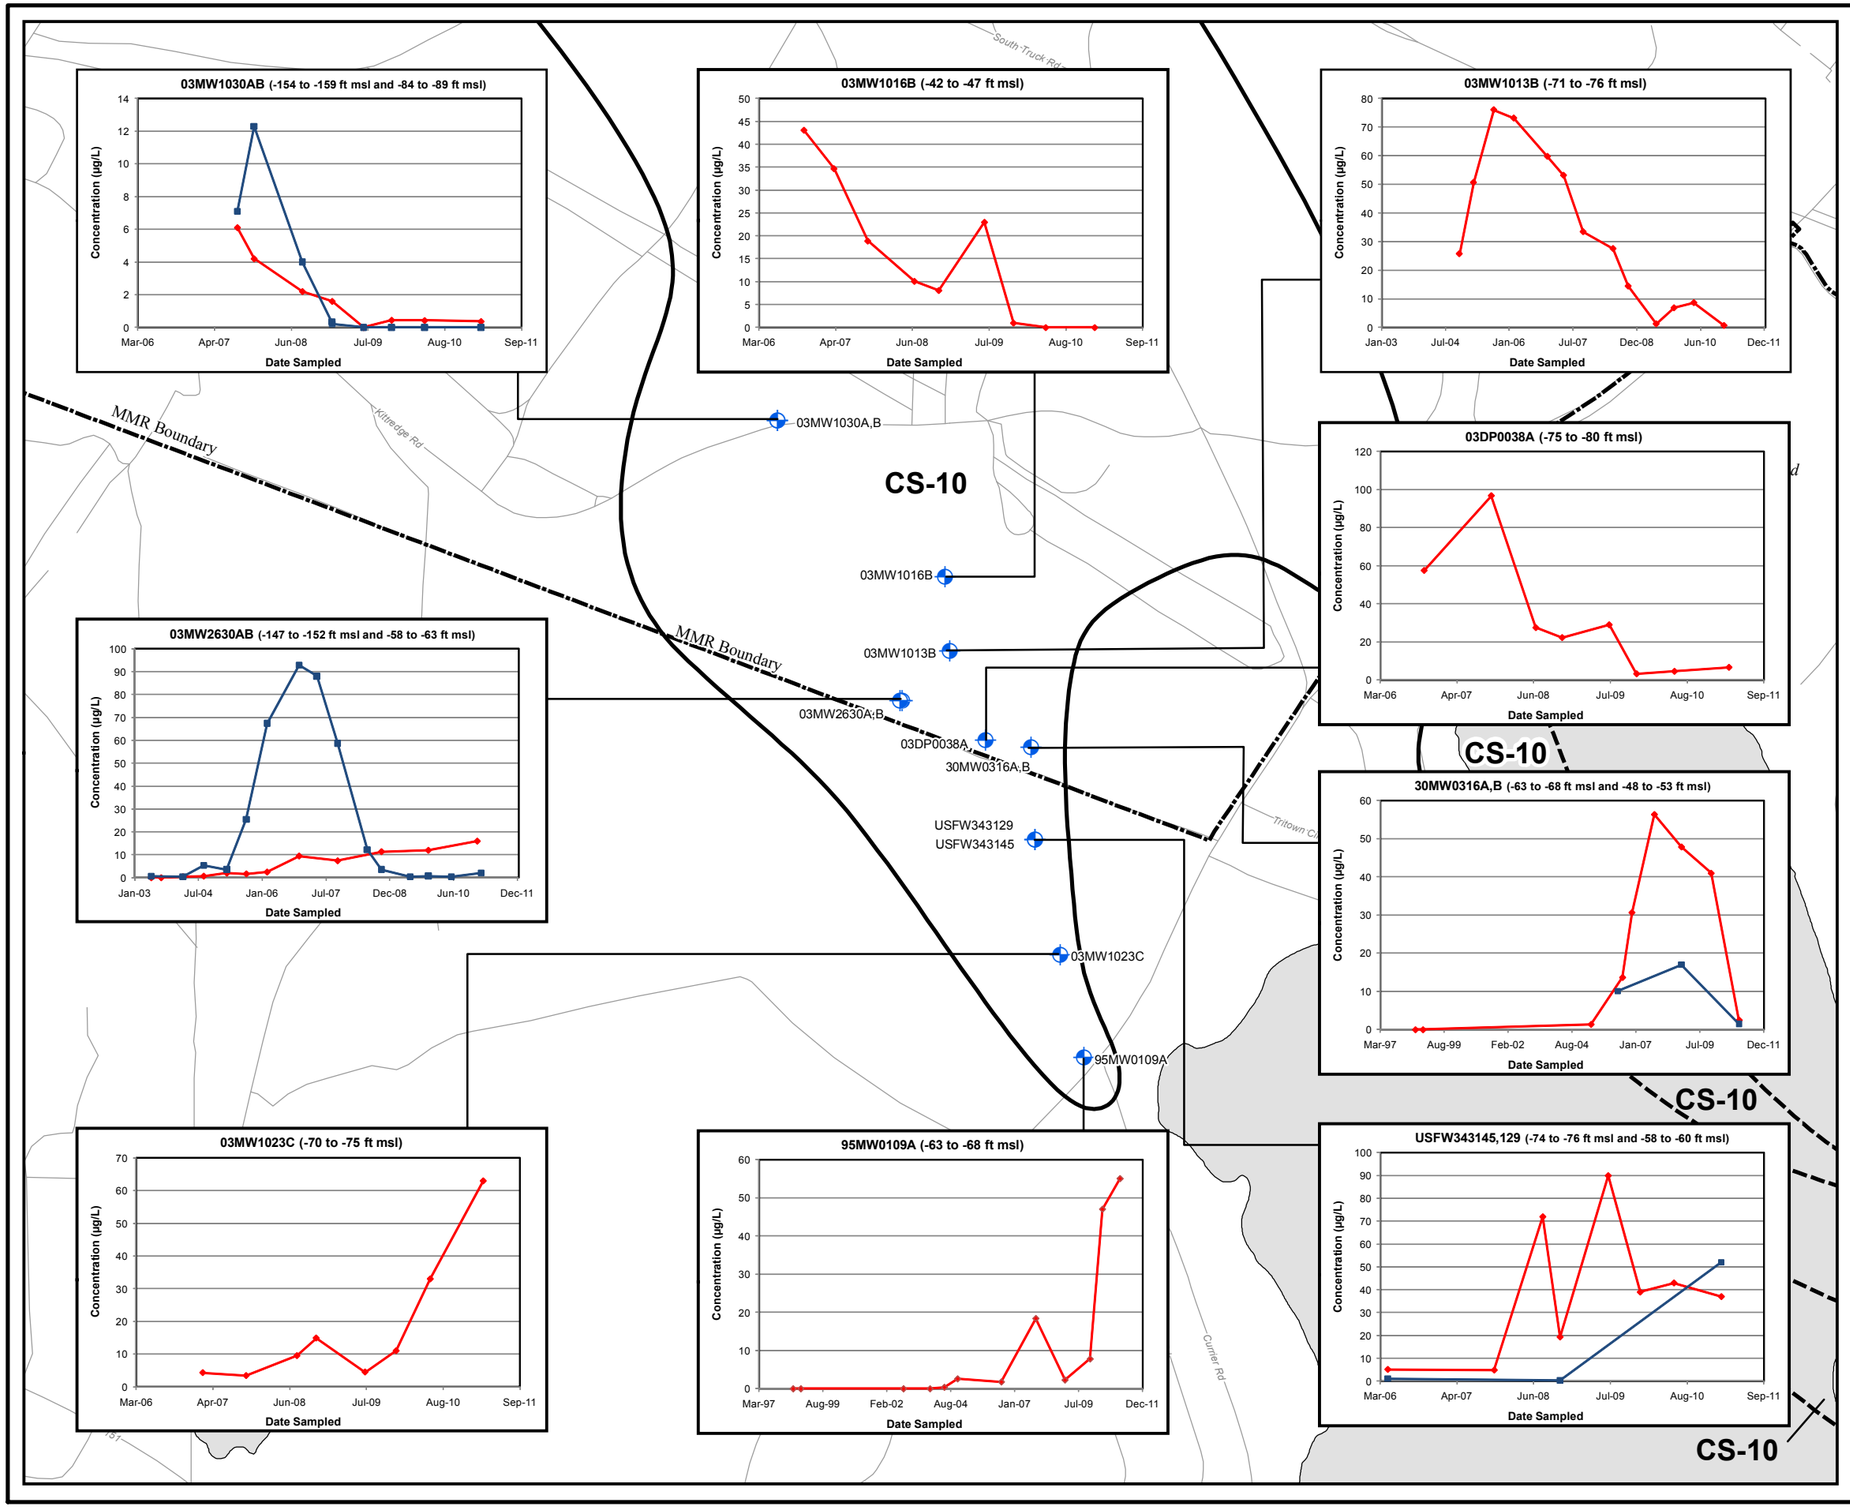
- MCL exceedances were observed in only two wells: 03DP0037A (7.4 µg/L) and 03MW1026A (20 µg/L).
- Notable decreases in TCE concentrations: 03MW1013B (8.6 µg/L to BRL) and 03MW1026A (50 to 20 µg/L).

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

CS-10 Southern Trench Results:

TCE concentrations in the Southern Trench Base Boundary Wells were relatively consistent with the previous sampling event

- Notable decreases in TCE concentrations: 03MW1017B (16 to 4.2 µg/L), 30MW0316A (41 to 2.5 µg/L) and 30MW0316B (17 to 1.5 µg/L).
- Current maximum TCE concentration at the base boundary is 17 µg/L at USFW572146.



CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

CS-10 Southern Trench Results:

TCE concentrations Downgradient of the Base Boundary generally increased

- Notable increases in TCE concentrations: 03MW1023C (33 to 63 µg/L), 95MW0109A (47 to 55 µg/L), USFW343129 (BRL to 52 µg/L), USFW347131 (2.3 to 13 µg/L) and USFW347145 (2.3 to 55 µg/L).
- Notable decrease in TCE concentrations: 03MW1058C (21 to 1.5 µg/L) and USFW343145 (43 to 37 µg/L, maximum of 90 µg/L in 2009).

03EW2112 has been operating at 100 gpm with a packered configuration since January 2011; TCE influent concentrations increased from 1 to 2 µg/L in 2011.

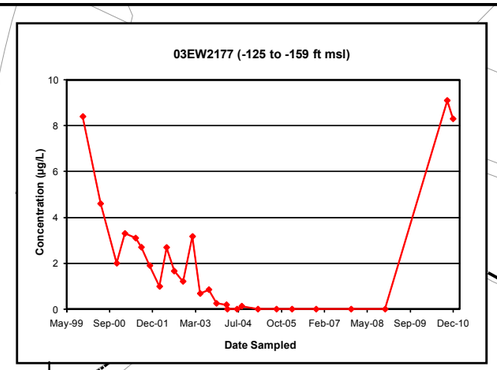
Extraction Wells



- TCE influent concentrations exceeded the MCL in two operational EWs: 03EW2173 (21 µg/L) and 03EW2174 (7.5 µg/L).
- TCE concentrations generally increased; maximum increase was observed at 03EW2173 (8.5 to 21 µg/L).
- TCE concentrations decreased at 03EW2174 (12 to 7.5 µg/L).
- PCE was not detected above the reporting limit in any extraction well.
- Sandwich Road extraction wells operated between 93 and 99 percent of their design flow rates between January and June 2011.
- Two off-line extraction wells (03EW2176 and 03EW2177) were turned back on line in 2011 after MCL exceedances were observed in 03EW2177; investigation is ongoing.

CS-10 Sandwich Road - Results:

Plant (January to June 2011)

- TCE influent concentrations ranged between 6.20 µg/L and 7.08 µg/L.
- PCE influent concentrations were BRL.
- ETR system removed approximately 8 lbs of TCE and 0.4 lbs of PCE between January and June 2011, and 1,019 lbs of TCE and 23 lbs of PCE since system startup.
- Approximately 0.14 billion gallons of groundwater from the CS-10 Sandwich Road extraction wells were treated at the SRTF and 3 carbon exchanges were completed between January and June 2011.

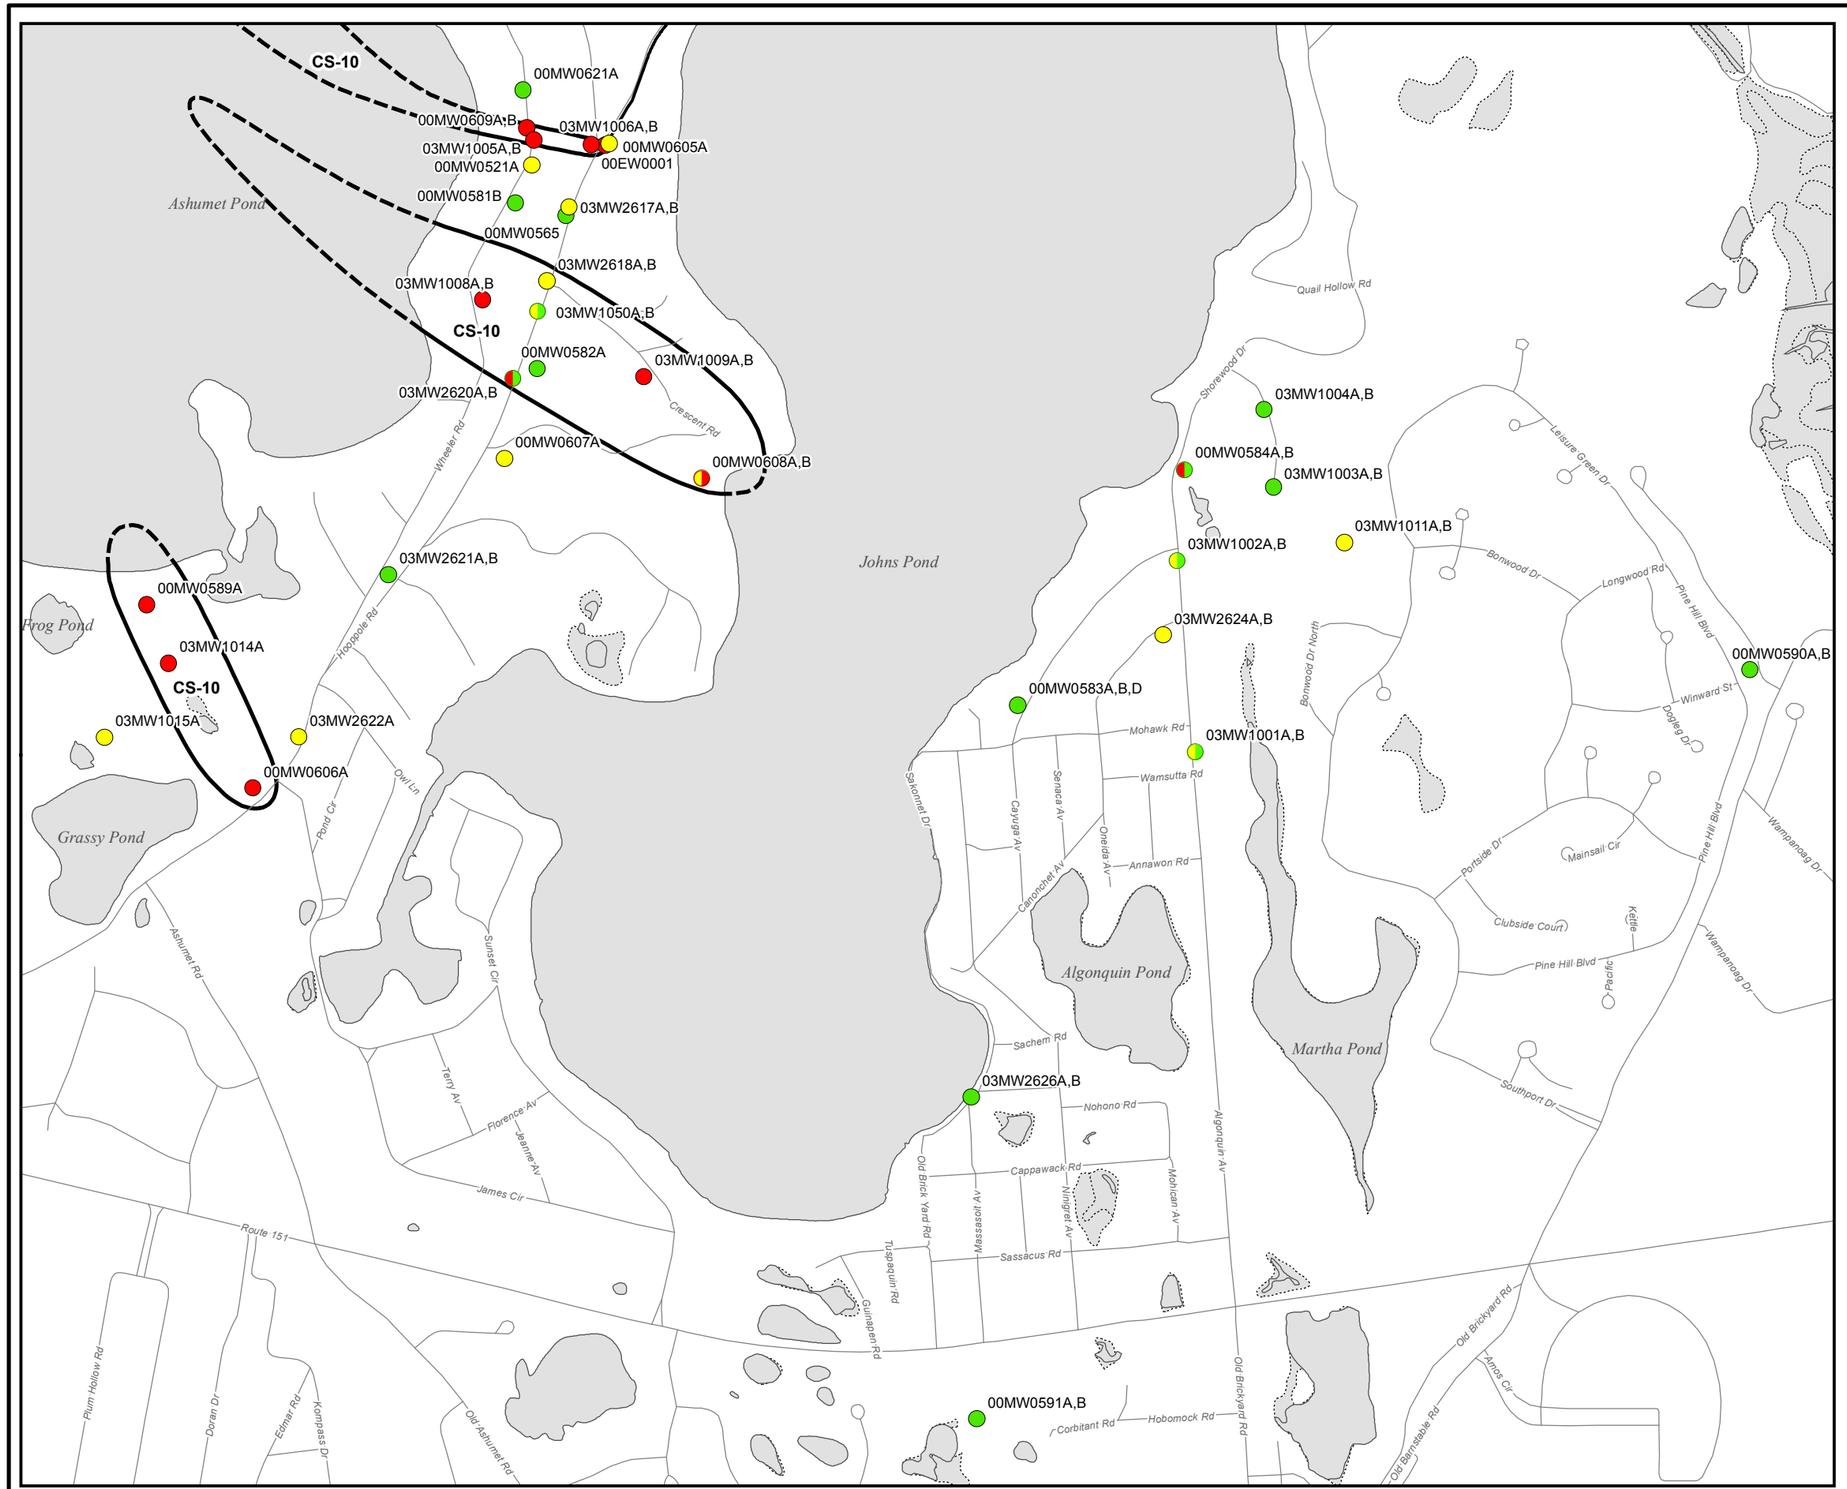
Notes:

1) The estimated air emissions presented in this table are based on the assumption that until 4/30/2009, the power used to operate the MMR remedial systems was provided by the Mirant Canal Station power plant in Sandwich, MA. This power plant primarily produced electricity generated by the combustion of fuel oil and has been off-line since 5/1/2009. Starting on 5/1/2009, air emissions are based on electricity generated by the average mix of power sources in Massachusetts. Air emissions were calculated using MMR utility data from AFCEE's Metrix 4 Utility Accounting Software (http://www.abraxasenergy.com/metrix4.php) and emission factors obtained from the following websites:
http://www.csgnetwork.com/elecpowerpolcalc.html
http://www.metrixcentral.com/EmissionsCalculator/Emissions%20Factors%202004.pdf
2) Emissions offset by purchases of electricity from renewable sources beginning 7/1/2008.
3) Emissions offset by operation of AFCEE-owned wind turbine beginning on 12/2/2009.



Key:
COC = contaminant of concern
CO_2 = carbon dioxide reported in tons
CS-10 = Chemical Spill-10
MMR = Massachusetts Military Reservation
MWh = megawatt hours
NO_x = nitrogen oxides reported in pounds
PM-10 = particulate matter with a diameter of 10 micrometers or less reported in pounds
SO_2 = sulfur dioxide reported in pounds
VOCs = volatile organic compounds reported in pounds

CS-10 Sandwich Road - Results:

Monitoring Wells

- Maximum TCE concentration of 42 µg/L was detected in 03MW0224E.
- TCE concentrations were generally consistent with previous sampling events; one notable decrease was observed at 03MW0209E (230 to 41 µg/L) and one notable increase was observed at 03MW2628A (ND to 4.2 µg/L).
- TCE concentrations in trailing edge well 03MP0091A decreased below the MCL for the first time (from 12 to 2.8 µg/L); previous maximum concentration of 1,500 µg/L was observed at this well in 2001.
- PCE was detected at concentrations in two wells: 03MW0206G (1.3 µg/L) and 03MW0224E (3.6 µg/L).

Northern Lobe:

Monitoring Wells/Surface Water

- TCE concentrations in the Northern Lobe fluctuated compared to concentrations detected in the previous sampling event.
- Notable increases were observed at two wells: 03MW1005A (210 to 259 µg/L) and 03MW1005B (45 to 182 µg/L).
- Notable decreases were observed at three wells: 00MW0609A (230 to 185 µg/L), 03MW1006A (180 to 22 µg/L), and 03MW1006B (270 to 69 µg/L) .
- PCE was detected above the reporting limit at two wells: 03MW1005A (1.7 µg/L) and 03MW1005B (1 µg/L).
- Surface water sample was collected from former discharge area in Johns Pond in July 2011 and TCE was not detected.

CS-10 NORTH CENTRAL LOBE TCE CONCENTRATION TRENDS

AFCEE - Massachusetts Military Reservation

29 September 2011 Technical Update Meeting

CH2MHILL®

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

North Central Lobe:

- TCE concentrations exceeded the MCL in six wells at concentrations ranging from 5.4 µg/L (03MW1009B) to 31 µg/L (03MW1008B).
- TCE concentrations generally decreased; notable decreases in TCE concentrations were observed in three wells: 03MW2618B (24 to 4.5 µg/L), 03MW2620A (15 to 7.3 µg/L), and 03MW1050A (12 to 4.5 µg/L).
- PCE was detected in five wells at concentrations ranging from 1.2 µg/L (00MW0608A) to 4.7 µg/L (03MW2620A).
- PCE concentrations also generally decreased; one notable decrease was observed at 03MW2620A (9.7 to 4.7 µg/L).

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

Southern Lobe:

- TCE concentrations exceeded the MCL in three wells:

  00MW0589A (23 µg/L), 03MW1014A (35 µg/L), and 00MW0606A(8.8 µg/L).

- PCE concentrations exceeded the MCL in two wells: 00MW0589A (9.6 µg/L) and 03MW1014A (8.7 µg/L).

- Notable decreases in TCE (67 to 23 µg/L) and PCE (26 to 9.6 µg/L) concentrations were observed at 00MW0589A and in TCE at 00MW0606A (3.4 to 8.8 µg/L).

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

East Side of Johns Pond:

- Background: In 2003 TCE concentrations at 00MW0584A (screened from 281 to 286 ft bgs) increased from ND to 5.1 µg/L and initiated a leading edge investigation. An Eastern Lobe was delineated in 2004 based on MCL exceedances at three wells: 00MW0584A, 03MW1003B, and 03MW1011B.

- TCE concentrations decreased below MCL at 00MW0584A in 2004 and at wells 03MW1003B and 03MW1011B in 2005 and the Eastern Lobe was no longer delineated.

- In 2011, TCE concentrations at 00MW0584A increased above the MCL to 6.2 µg/L; re-sampled well in July 2011 and results were confirmed (7.6 and 6.5 µg/L).

- TCE was not detected in 03MW1003B and was BRL in 03MW1011B. Results in other monitoring wells located on the east side of Johns Pond were also consistent with the previous sampling event.

Notes:

BRL = below reporting limit

J = Analyte is present but the reported value may not be accurate or precise (estimated).

U = Analyte was not detected at the specified detection limit.

S = Sample was analyzed via the screening level VOC analytical approach.

Bold values indicate MCL exceedances.

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

Conclusions:

- CS-10 plume contamination distribution is complicated, several high concentration lobes upgradient of 03EW2102 and higher concentration areas in the areas of extraction wells 03EW2103, 03EW2104, and 03EW2105 have been identified. MCL exceedances have also been detected outside the current CS-10 plume boundary.
- Based on the draft revised 2011 plume shell, the CS-10 In-Plume system is still meeting RAO's and contamination located to the east of the current plume boundary is located within the Sandwich Road capture zone.
- Maximum TCE concentrations are located upgradient of 03EW2102 and 03EW2105, influent concentrations at 03EW2102 remain consistently high.
- TCE concentrations at 03EW2106 and in the area of 03EW2106 support taking this well out of operation.
- Higher concentrations previously detected downgradient of 03EW2111 have decreased and contamination appears to have migrated downgradient of the base boundary toward 03EW2112.

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

Conclusions (continued):

- Contamination has migrated past the base boundary to the east of the Sandwich Road fence. Eastern wells 03EW2176 and 03EW2177 have been turned back on while a data gap investigation is ongoing in this area.
- TCE influent concentrations at the Northern Lobe extraction well (00EW0001) are consistent with high TCE concentrations in upgradient wells; the extraction well is containing the plume and operating as designed.
- Concentrations in the North Central Lobe and the Southern Lobe are consistent with previous results indicating the overall delineation of these leading edge lobes are adequately characterized.
- TCE concentrations at one well on the east side of Johns Pond (00MW0584A) increased above the MCL. This well is screened above bedrock, contamination at this location will not have any impact on the Mashpee Water Supply well. TCE concentrations at other monitoring wells in this area were consistent with previous sampling events.

CS-10 SPEIM/LTM
Biennial Data Presentation
29 September 2011 Technical Update Meeting

Recommendations:

- Reduce sampling frequency of semiannual southern trench area wells to annual. CS-10 extraction wells would still be sampled semiannually.
- Continue groundwater sampling at selected ISCO pilot test wells to further evaluate the concentration trends for TCE, selected metals, and TDS.
- Continue operating Sandwich Road extraction wells 03EW2176 and 03EW2177 at interim flow rates (75 and 50 gpm, respectively).
- Continue operating 00EW0001 at the higher flow rate (225 gpm) until influent concentrations decrease.
- Increase sampling frequency of 00MW0584A from biennial to annual.
- Revise the plume boundary and finalize the TCE plume shell after the data gap investigation is completed.

Subject: **PILOT TEST OF BOREHOLE GEOPHYSICAL LOGGING METHODS TO IDENTIFY LITHOLOGY**	Issued By: Nigel Tindall CH2M HILL TECHNICAL SERVICES GROUP MANAGER

ITEM	REMARKS
1.0	**INTRODUCTION** This project note presents the results of a field pilot test of geophysical logging methods at the Chemical Spill-10 (CS-10) plume at the Massachusetts Military Reservation (MMR) (Figure 1). The purpose of the pilot test was to assess the effectiveness of natural gamma radiation and electromagnetic (EM) induction geophysical logging methods to help identify the lithology of geologic units at existing MMR monitoring wells where no geologic logging was completed during well installation. Specifically, the test was completed to determine if geophysical techniques could identify fine-grained units, adjacent to existing monitoring wells, which would aid in the understanding of the presence and distribution of low-hydraulic conductivity (i.e., fine-grained) units in the aquifer. As part of the recent CS-10 data gap investigation, various means of subsurface geologic characterization have been utilized to more fully delineate the finer-grained units in the aquifer below the MMR. Borehole geophysical data were identified as having the potential to supplement other site characterization data to improve the hydrogeologic conceptual site model and to recalibrate the groundwater flow model. The low hydraulic conductivity units in the aquifer directly influence the plume's fate and transport. Therefore, having a good understanding of their distribution is important in assessing the role these low conductivity units may have on aquifer restoration. For further information about the CS-10 plume refer to the CS-10 Groundwater Plume Conceptual Site Model (AFCEE 2010) and the CS-10 2010 Summary Letter Report (AFCEE 2011b). This project note provides a summary of the results of geophysical logging at two existing monitoring wells and one geophysical boring, installed using rotosonic drilling techniques with continuous soil coring and detailed logs of the sediments encountered during drilling. The natural gamma radiation and EM logs obtained at each location were compared to the lithologic soil boring logs to determine the appropriateness of using these geophysical methods as a means of interpreting lithologic information at existing monitoring wells installed without any soil sampling or logging. An evaluation of the results was used to determine the usefulness of these two geophysical logging methods to support the Air Force Center for Engineering and the Environment (AFCEE) System Performance and Ecological Impact Monitoring (SPEIM) program at MMR.

ITEM	REMARKS
2.0	**OVERVIEW OF THE TECHNOLOGY** After considering a range of geophysical methods natural gamma radiation and EM borehole logging were determined to be the most suitable, versatile, and effective techniques to have the potential to identify the location of fine-grained lithologic units adjacent to existing monitoring wells. Other potentially useful techniques evaluated included surface geophysical methods, neutron logging, and petrophysical analysis of major lithologic units. These techniques were ruled out because of higher cost, increased complexity, and/or well diameter limitations. Natural gamma radiation logs measure naturally occurring gamma radiation emitted by soil particles. The most common emitters include potassium-40, uranium-238, thorium-232, and their daughter products. These emitters are more concentrated in fine-grained material and are typically associated with clay minerals. A sodium iodide crystal mounted in a sonde acts as the natural gamma radiation emission detector. As the detector is slowly lowered down the well, it produces a flash of light when the crystal comes in contact with natural gamma radiation emissions. The flashes, referred to as 'counts,' occur at a frequency synonymous with the level of gamma radiation being emitted by the material encountered at certain depths, which in turn increases with increasing clay content in the adjacent soil. Natural gamma radiation logs are represented graphically by plotting the counts per second versus depth. Depth intervals with higher counts per second are representative of finer grained units that contain more clay minerals. Once interpreted, these logs can provide useful grain size, lithology, and unit thickness data to supplement subsurface geologic characterization (U.S. Geological Survey 1990). EM induction operates by recording the electrical conductivity or resistivity of the natural material and porewater surrounding a particular well. Because freshwater has a low conductivity (ranges from approximately 50 to 300 microsiemens per centimeter in CS-10 groundwater), it is assumed that conductivity measurements recorded in freshwater wells reflect the characteristics of the surrounding natural material only. Coarse-grained materials such as sand and gravel generally produce lower conductivity measurements, while fine-grained materials like silt and clay produce higher conductivity measurements. Logs are represented graphically as plots of conductivity versus depth. These graphs provide useful information for interpreting subsurface geology (U.S. Geological Survey 1990).
3.0	**TECHNICAL APPROACH** Two 2.5-inch diameter PVC monitoring wells and one soil boring completed with a closed 4-inch diameter PVC casing (03MW1064A and 03MW1067A, and 03GB1060, respectively) were selected for pilot testing of natural gamma radiation and EM logging (**Figure 2**). Drilling at all three locations had been conducted during 2009/2010 using rotosonic drilling techniques. Continuous soil samples were collected and logged at each location from the water table to bedrock following the standard technical procedures contained in the AFCEE MMR Quality Assurance Program Plan (QAPP) (AFCEE 2011a). Soil boring logs indicating soil descriptions generated from conventional Unified Soil Classification System (USCS) soil logging procedures, and well construction diagrams for the logged locations are provided in **Attachment A**. It is noted that a second soil boring (03MW1060A) was advanced approximately 10 feet from

ITEM	REMARKS
	03GB1060. Logging information from 03MW1060A was also considered in the evaluation of the geophysical logs from 03GB1060 and the soil boring from 03MW1060A is also included in **Attachment A**. The pilot test locations, all shown on **Figure 2**, were selected based upon well depth and the variation in lithology (i.e., the presence of finer grained silt and clay units) as determined by a review of the available soil boring logs. The pilot test was designed to log the selected locations using natural gamma radiation and EM induction methods and compare interpreted results to known lithologic information. In September 2010, Geophysical Applications, Inc., under subcontract to CH2M HILL, performed logging from ground surface to the bottom of each test location using a Mount Sopris model 4MXB digital logging winch and Mount Sopris EM induction and polygamma probes. A report completed by Geophysical Applications, Inc. is included as **Attachment B**. The natural gamma radiation log was recorded using a downward logging speed of approximately six feet per minute, to help identify subtle natural gamma radiation variations that typically indicate changes in clay mineral content. EM induction logs were recorded while lowering the probe at 10 to 20 feet (ft) per minute. Depth measurements were accurate within approximately 0.2 feet, and data were recorded at depth increments of 0.1 ft throughout each borehole. The EM induction probe allowed for measurement of bulk electrical-conductivity variations outside the PVC casing installed at each location.
4.0	**RESULTS** The results from the geophysical logging pilot test included geophysical log data and generalized log interpretations from Geophysical Applications, Inc (**Attachment B**). The natural gamma radiation logs, EM induction logs and inferred lithologies from each location, merged onto one WellCAD plot to aid in data correlation, are presented in Appendix A of **Attachment B**. The following sections present a comparison of the interpretation of lithology from the geophysical logs to the lithologies recorded during drilling at each location (**Attachment A**). In the natural gamma radiation logs (shown in the first column of each log plot in Appendix A of **Attachment B**), inflections toward the right represent increased natural-gamma decay counts likely due to the increased presence of finer grained clay minerals, or possibly other minerals containing potassium, thorium, or uranium. On EM induction logs (shown in the second column of each log plot), gradual inflections toward the right generally represent increases in the electrical conductivity of materials outside the PVC casing or screen, which can represent electrically-conductive minerals (e.g. clay), or electrically-conductive pore fluids (e.g., saline water). The third column on the plots present inferred lithologies obtained from a cross-plot of natural gamma radiation decay counts versus EM conductivity; these cross-plots are included in Appendix A of **Attachment B**. Each data point plotted on a cross-plot diagram represents natural gamma radiation and EM conductivity values from a single measurement depth. Three boxes were drawn on each cross-plot, representing three groups of possible lithologies: sand, silt, and clay.

ITEM	REMARKS

03GB1060

At 03GB1060, EM conductivity values recorded during logging were generally lower compared to the other two logged wells. Geophysical Applications speculated that this lower range in EM values represented generally lower-conductivity groundwater near this well (Attachment B). However, after further inspection of field records, groundwater conductivity values at all three locations were similar; it is possible that this lower range of EM values is related to the difference in how the borehole was completed at 03GB1060 (i.e., a 4-inch diameter PVC casing versus 2.5-inch diameter PVC well clusters). Layers of silt and clay materials, judging from moderate to high gamma and EM conductivity values on the geophysical logs, were interpreted near the ground surface, between 12-92 ft below ground surface (bgs), at 212-214 ft bgs, 229-241 ft bgs, and as localized, small interbedded sand and silt/clay layers at 245, 260, 267, 270, and 312-320 ft bgs. Lower EM conductivity and natural gamma radiation data values were judged to represent mostly sand between 92-229 ft bgs and 241-312 ft bgs.

Some of these intervals correspond with the lithology logged at 03GB1060, particularly a silt and sand lens logged at approximately 212-213 ft bgs (at 03MW1060A), interbedded sands and silts between approximately 227-247 ft bgs (03MW1060A), and silt between 230-244 ft bgs (03GB1060). A silt unit logged at 272-274 ft bgs on 03MW1060A may correspond to silt and clay materials interpreted from the geophysical logs at 270 ft bgs; however, a similar silt/clay unit was not logged at 03GB1060. In general, the geophysical logs indicate that sediments containing a higher proportion of finer grained materials are present from approximately 212-240 ft bgs and near 270 ft bgs and this interpretation corresponds relatively well with the sediments logged at 03GB1060.

03MW1064A

Erratic variations in natural gamma radiation decay values at 03MW1064A suggest interbedded clay and either silt or sand beds, particularly at depths less than 54 ft bgs; no soil samples were collected from these shallow intervals during drilling so no comparison can be made. Silt materials, as represented by moderate EM conductivity values, were interpreted to exist at depths less than 146 ft bgs, although natural gamma radiation values were relatively low suggesting lower proportions of clay minerals. A transition zone of sand and clay was interpreted at 146-151 ft bgs, above a predominantly sandy interval present from approximately 151-215 ft bgs. Lenses of clayey minerals, represented by locally high natural gamma radiation values, were interpreted at 13, 16-20, 36, 180, 192, and 206-211 ft bgs. Lower EM conductivity and high to variable natural gamma radiation decay values were judged to represent sand/clay mixtures from 216-257 and 268-282 ft bgs, while both high EM conductivity and natural gamma radiation decay values were interpreted to represent a silt and clay interval between 257-268 ft bgs.

An anomaly pattern observed near 122 ft bgs was interpreted from the geophysical logs as a metallic object, possibly a tool or other object that might have fallen into the annular space surrounding the borehole during drilling or well construction, as metallic materials were not utilized in well construction.

ITEM	REMARKS

Soil boring logs from sonic drilling at this location do not indicate the presence of silty material transitioning to sand; rather, sand with little fines is the predominant logged material shallower than 200 ft bgs which is consistent with the relatively low natural gamma radiation readings at least through 170 ft bgs. While no clay lenses were logged in the first 200 ft, it is noted that low sample recovery was observed at a couple sample intervals. A silt interval is logged from approximately 206-215 ft bgs, corresponding with the geophysical interpretation of fine-grained materials at 206-211 ft bgs. Silts and sand/silt/clay mixtures were logged from approximately 217-275 ft bgs, somewhat corresponding with the sand/clay and silt/clay intervals interpreted from the geophysical data within this depth interval. Finer-grained silts and clays, including interbedded clay stringers from 262-265 and at 269 ft bgs and a clayey silt interval from approximately 272-273.5 ft bgs were logged during drilling. Below 275 ft bgs, the material logged during drilling was predominantly sand with no clay as was interpreted from the geophysical data, but low recovery and possible drilling 'slough' may have affected logging in this interval. In general terms, the geophysical logging indicates an increase in the proportion of fine grained material from approximately 200-270 ft bgs and this observation compares relatively well with the sediments logged during drilling.

It is noted that three monitoring wells were installed at the 03MW1064A location and as part of well construction a bentonite clay "seal" is installed in the borehole above the well's filter pack. Bentonite clay is also installed in the borehole to seal off significant silt or clay units in the aquifer to eliminate the potential for the vertical migration of contaminants. The bentonite clay used has the potential to be a source of gamma emitters and may result in an increase in the gamma reading adjacent to the bentonite seal. At 03MW1064, bentonite was installed in the annular space of the borehole between 187-197.5 ft bgs, 226-233 ft bgs, 257-277.5 ft bgs, and at the bottom of the borehole from 302-309 ft bgs (which is below the bottom of the well that was geophysically logged). Inspection of the response in the gamma log at the intervals where the bentonite seal was placed at 03MW1064 did not identify any clear increase in gamma values (or a response in the EM log). It is possible that the gamma readings associated with the natural formation exceed the gamma values associated with the bentonite and therefore the effects due to the presence of the bentonite are masked.

03MW1067A

At this location low EM conductivity values were interpreted to represent mostly sand at depths less than 60 ft deep, with clayey intervals identified near 6 and 13-16 ft bgs based on gamma readings. Between 61-88 ft bgs, distinctly higher EM conductivity values were interpreted to represent silty materials (or possibly pore fluids with higher electrical conductivity), and localized increases in natural gamma radiation decay values at 58-67 ft bgs were interpreted as an increase in clay-mineral content. Soil sampling commenced at 62 ft bgs and was logged as predominantly sand throughout this interval; however the bentonite seal for monitoring well 03MW1067C was installed between 57-67 ft bgs and the observed increase in gamma values is likely related to the bentonite seal at this interval. It is also noted that groundwater conductivity readings were

ITEM	REMARKS
	elevated in the groundwater vertical profile sample collected from 80-85 ft bgs suggesting the shallow groundwater in this area may be impacted by road salting activities nearby and hydraulically upgradient (i.e., north). The presence of sodium chloride at the water table would result in an increase in EM conductivity values. Moderate EM conductivity values from 88-223 ft bgs were interpreted to represent sand-silt mixtures; within this area, localized areas of increased natural gamma radiation values (at 173-176, 198, 203-205, and 217-221 ft bgs) were interpreted to have higher clay content. Below 223 ft bgs, higher EM conductivity and natural gamma radiation data values suggest the presence of silt with sand and some clay, particularly between 227-238 ft bgs where natural gamma radiation data values were increased. Bentonite seals were placed in the annual space of the borehole from 167-177 ft bgs and 227-237 ft bgs. It is likely the increased gamma readings noted above from 173-176 ft bgs and 227-238 ft bgs are linked to the gamma emitters from the placed bentonite clay. The soil boring log for 03MW1067A indicates that most material shallower than 200 ft bgs is sand with much less silt than inferred from the geophysical logging data. Silt and silty sand units interbedded with sand units were logged from approximately 200 to 300 ft bgs, corresponding relatively well with the geophysical data interpretation which indicated silt/sand/clay mixtures below 223 ft bgs. A silt unit logged from 225 to approximately 237 ft bgs likely correlates with the inferred clay unit from 227 to 238 ft bgs described above (although the gamma response is also influenced by the presence of the bentonite seal), and a silt and clay lens logged at approximately 254-256 ft bgs correlates with clay interpreted from geophysical data at 254-257 ft bgs. In general, the presence of finer grained sediment reported below approximately 200 ft bgs on the soil boring log correspond well with the geophysical logging data, although the presence of bentonite seals in the borehole should be taken into consideration during data analysis.
5.0	**CONCLUSIONS** Data collected during this pilot test indicate that the geophysical logging techniques tested have the potential to provide useful information about the subsurface geology at well locations where no detailed lithologic information was collected during drilling. At the three pilot test locations with known lithologic information, the interpretation of the geophysical logging results corresponded fairly well with the logged soil data, particularly at depths below 200 ft bgs or in sections of interbedded finer and coarser-grained material (i.e. alternating sands and clays or silts). Many of the finer-grained intervals identified during the geophysical logging corresponded to similar intervals in the soil logs to within a few feet; examples include a silt unit at 230-240 ft bgs at 03MW1060A (fine grained material interpreted from 229 to 241 ft bgs from the geophysical data), and a silt unit at 206-215 ft bgs at 03MW1064A (fine-grained material interpreted from 206-211 ft bgs from the geophysical data). A response in the gamma log at intervals where bentonite seals were placed in the borehole annular space during well construction was observed. Therefore, care should be taken when interpreting gamma logs collected from existing wells where bentonite seals are known, or have the potential, to be present.

ITEM	REMARKS
	At all three logging locations in this pilot test, the lithologic interpretation of the geophysical results at shallow depths (generally under 100 ft bgs) were inconsistent with the soil logged during drilling. Geophysical data was generally interpreted to represent finer-grained silts, but soil logs indicated only sands down to these depths. The interpretation of the cross-plots did not account for the potential for different EM responses in the saturated versus unsaturated zones which may have contributed to the assigned of a finer grained lithological classification in the shallower zones. In general, the interpretation of the geophysical data inferred a greater amount of silt and clay than was logged during drilling. The report from Geophysical Applications, Inc. (**Attachment B**) indicated that the natural gamma radiation logs may have depicted more-subtle variations in clay mineral content than could be interpreted from the visual inspection of samples collected during drilling, thus some fine layers inferred from the geophysical natural gamma radiation logs may not have been visibly observed in the soil samples described by the field geologist. Other survey limitations identified by Geophysical Applications, Inc., and inherent to the logging process included EM anomalies that can be caused by metallic objects (e.g., well construction materials, miscellaneous tools, iron fragments, or underground utilities), which may mask subtle variations caused by changes in lithology. Also, inferred lithologic variations based solely upon natural gamma radiation and EM conductivity variations are approximate. Overall, the data produced from logging the existing monitoring wells at MMR using the geophysical techniques described herein have the potential to be useful in identifying major fine-grained units and marker units consistent across sections of the aquifer below the MMR. These geophysical logging technologies have the potential to provide additional site characterization data to help fill data gaps where no detailed lithologic information exists. This may be particularly important during the development of groundwater flow models where a sound hydrogeologic conceptual site model is the basis of the model creation and calibration. For example, these geophysical techniques would be well suited to fill data gaps around the periphery of the model domain where no existing lithologic data is available (assuming deep monitoring wells are present). In addition, even if existing lithologic data is available, the data set could be supplemented using these geophysical techniques thus improving the overall conceptual site model. Other benefits to the technologies include ease of use and efficiency: relatively low cost compared to other data collections techniques (and especially rotosonic drilling); the logging equipment can be used in 2-inch or larger wells and many wells can be logged relatively quickly. However, due to the subtle differences in gamma and EM response noted in the pilot test log interpretation and the complicating effects of bentonite seals installed during well completion, experienced personnel should be used to collect and interpret this geophysical data.
6.0	**RECOMMENDATIONS** Geophysical logging using natural gamma radiation and EM conductivity was able to identify, with mostly successful results, the presence and approximate extent of several fine-grained units (e.g., silty-sand, silt, and clay lithologic units) within the three existing locations selected for this pilot test. In many instances, the accuracy of interpreted results would be sufficient to provide

ITEM	REMARKS
	information about the subsurface geology where detailed soil boring logs do not exist, particularly for supplementing the dataset used for groundwater flow model construction. Therefore, utilizing the geophysical logging techniques included in this pilot test to supplement existing subsurface geologic data should be considered when designing site characterization efforts. The decision to include the geophysical logging techniques tested depends on the overall data quality objectives of the planned investigation including the extent of the data gaps being filled, the degree of certainty required in the characterization, and how the data are to be used in the overall remedial decision making process.

Subject: Borehole Geophysics Logging Report
Natural Gamma & EM Conductivity Tests
Massachusetts Military Reservation
Sandwich, Massachusetts

phone: 508-968-4670
email:nigel.tindall@CH2M.com

Dear Mr. Tindall:

This report describes borehole geophysics logging performed by Geophysical Applications, Inc. at the above-noted site, to help CH2M Hill identify lithologies encountered by three screened monitoring wells.

The logged wells included: 03GB1060, 03MW1064A, and 03MW1067A. The contracted log suite consisted of natural gamma and EM conductivity, as described below.

CH2M Hill provided a log describing lithologic variations observed during drilling at 03MW1067A, to help guide our inferences regarding EM and gamma anomalies that might represent sand, silt, and clay. Lithologic variations at the other two logged wells were based solely upon the recorded geophysical log data.

METHODS OF INVESTIGATION

Survey Control

All borehole log depths were referenced to ground surface at each well. The geophysical logging winch contains an optical depth encoder, to maintain depth measurements accurate within approximately ± 0.2 feet throughout a borehole.

Borehole Geophysics Logging

A Mount Sopris model 4MXB digital logging winch and Mount Sopris EM induction and polygamma probes obtained all geophysical-log data. These logs were recorded at 0.1-foot depth increments, as determined by the logging winch's digital depth encoder.

The natural gamma log was recorded during the first logging run at each screened well, using a downward logging speed of approximately six feet per minute, to help identify subtle natural-gamma variations that typically indicate changes in clay mineral content.

Electromagnetic (EM) conductivity logs were also recorded in each well with a Mount Sopris polyinduction probe, at 0.1-foot depth increments. The EM induction logs were recorded while

lowering the probe at 10 to 20 feet per minute. The EM induction probe allows measurement of bulk electrical-conductivity variations outside a PVC-screened well. Sand will typically exhibit lower electrical conductivity than either silt or clay.

All geophysical log data were recorded on a laptop computer's hard drive, and copied to CD-ROM as a backup precaution.

Post-survey plot scales were adjusted to display as much detail as possible. All logs recorded in each borehole were merged onto one WellCAD plot, to aid data correlation.

Lithologic changes represented by variations in natural gamma and EM induction data values were inferred using WellCAD's crossplot software module.

Equipment Decontamination Procedures

Decontamination consisted of an Alconox scrub and tap water rinse of logging cables and probes between logging runs.

SURVEY LIMITATIONS

Measured geophysical-log depths are estimated to be accurate within ± 0.2 feet at this site, allowing for some slippage of the winch's depth-measurement wheel.

EM induction data values may be adversely affected by nearby metallic objects. EM anomalies caused by metallic objects may mask subtle variations caused by changes in lithology.

Inferred lithologic variations based solely upon natural gamma and EM conductivity variations are approximate.

RESULTS

Geophysical log data and generalized log interpretations are described below. Specific interpretations regarding inferred lithologic variations versus depth are listed in the "comments" column on each log plot.

All geophysical logs described in this report are presented in Appendix A.

Natural gamma logs are shown in the first column of each conventional log plot. Inflections toward the right represent increased natural-gamma decay counts, probably due to the presence of clay, or possibly other minerals containing potassium, thorium, or uranium.

EM induction logs are shown in the second column of each log plot. Gradual inflections toward the right generally represent increases in the electrical conductivity of materials outside the PVC casing or screen. These increases can represent electrically-conductive minerals (e.g. clay), or electrically-conductive pore fluids (e.g. saline water). Localized increases in EM conductivity near the top of each EM induction log may represent a shallow, steel well casing or other near-surface metallic objects.

Inferred lithologies based on natural gamma and EM induction data are summarized in each log plot's third column. These inferences were obtained from a crossplot of natural gamma decay counts versus EM conductivity; these crossplots follow each well's conventional log plot, in Appendix A. Each data point plotted on a crossplot diagram represents natural gamma and EM

conductivity values from a single measurement depth. Three boxes were drawn on each crossplot, representing three groups of possible lithologies: sand, silt, and clay.

Sand will typically exhibit low natural gamma decay counts, and relatively low EM conductivity (clean sand is electrically resistive, compared to silt or clay). Yellow shading with short gray dashes represents sand on the crossplots, and also in the "interpreted lithologies" column shown on each conventional log plot.

Silt typically exhibits higher electrical conductivity than sand, & lower natural gamma decay counts than clay. Short yellow and red dashes represent silt on the crossplots and "interpreted lithologies" column.

Clay will often exhibit high natural gamma decay counts, and moderate to high EM conductivity values. Natural gamma decays higher than 70 counts per second (cps) were judged most likely to represent clay minerals at these logged boreholes. Long light-grey dashes represent clay on the crossplots and "interpreted lithologies" column. Note that gamma decays higher than 70 cps overlap with both the "sand" and "silt" portions of each crossplot, indicating some clay in the presence of either sand or silt.

WellCAD's crossplot software module calculated the depth ranges that exhibit one or more of the sand, silt and clay lithologies, and exported that information to the conventional log plots' "interpreted lithologies" data column. Note that WellCAD does not calculate the proportions of sand/silt/clay; symbols shown in the "interpreted lithologies" data column indicate simply whether one or two of the sand/silt/clay lithologies were present at any given depth range.

Specific observations inferred at each logged borehole are summarized below.

<u>Well 03GB1060</u>

This monitoring well was located near the base's gym building.

EM conductivity values were considerably lower at this borehole compared to the other two logged wells. This may represent generally lower-conductivity groundwater near this well. Localized EM anomalies, especially near 60 to 70 feet deep, may represent small metallic objects utilized during well construction.

Slightly-higher natural gamma data values less than 16 feet deep indicate clay materials near the ground surface.

Moderate EM conductivity and natural gamma data values suggest mostly silty materials between 12 to 92 feet deep.

Lower EM conductivity and natural gamma data values are judged to represent mostly sand between 92 to 229 feet deep. A natural gamma increase probably represents a clayey layer near 212 to 214 feet.

Locally high natural gamma data values, and moderately high EM conductivity values, may represent mostly silt and clay near 229 to 241 feet.

Slightly lower EM conductivity values suggest mostly sand between 241 to approximately 312 feet deep. Localized natural gamma increases probably represent clay near 245, 260, 267, and 270 feet deep.

A steady increase in natural gamma data values from 312 to 320 feet deep probably represents increasing clay content between those depths.

Well 03MW1064A

This well was located on Herbert Avenue.

Erratic variations in natural gamma decay values suggest interbedded clay and either silt or sand beds, particularly at depths less than 54 feet deep.

The EM conductivity anomaly pattern near 122 feet deep strongly resembles a metallic object. Although CH2M Hill's review of the well construction diagram did not disclose metallic materials utilized in well construction, perhaps a metallic object or tool fell into the annular space surrounding the borehole during drilling or well construction.

Moderate EM conductivity values are judged to represent mostly silt materials at depths less than 146 feet deep. Localized natural gamma increases may represent clay minerals, particularly near 13, 16 to 20, and 36 feet deep.

Lower EM conductivity values may represent more sandy materials between 151 to 215 feet deep. A transition zone, with both sand and silt, may be present between 146 to 151 feet. Some locally high natural gamma data values probably represent more clay minerals near 180, 192, and 206 to 211 feet.

A combination of lower EM conductivity values and higher natural gamma decay values are judged to represent a mixture of sand and clay between 216 to 257 feet.

Locally higher EM conductivity and natural gamma data values may represent silt and clay near 257 to 268 feet deep.

Lower EM conductivities, and variable natural gamma decay values, are judged to represent interbedded sand and clay between 268 to 282 feet.

Well 03MW1067A

This well was located on West Inner Road.

Low EM conductivity values are interpreted to represent mostly sand less than 60 feet deep. Natural gamma increases near 6 and 13 to 16 feet deep probably represent clayey layers.

Distinctly higher EM conductivity values may represent more silt (or possibly pore fluids with higher electrical conductivity) between 61 to 88 feet deep. Locally higher natural gamma decay values between 58 to 67 feet probably represent some greater clay-mineral content.

Moderate EM conductivity values are judged to represent a mixture of sand and silt between 88 to 223 feet deep. Localized natural gamma increases likely represent clay materials, particularly near 173 to 176, 198, and 203 to 205 feet.

Higher EM conductivity and natural gamma data values suggest a mixture of silt and sand, with some clay. The highest natural gamma data values suggest clay minerals between 227 to 238 feet deep.

* * * * *

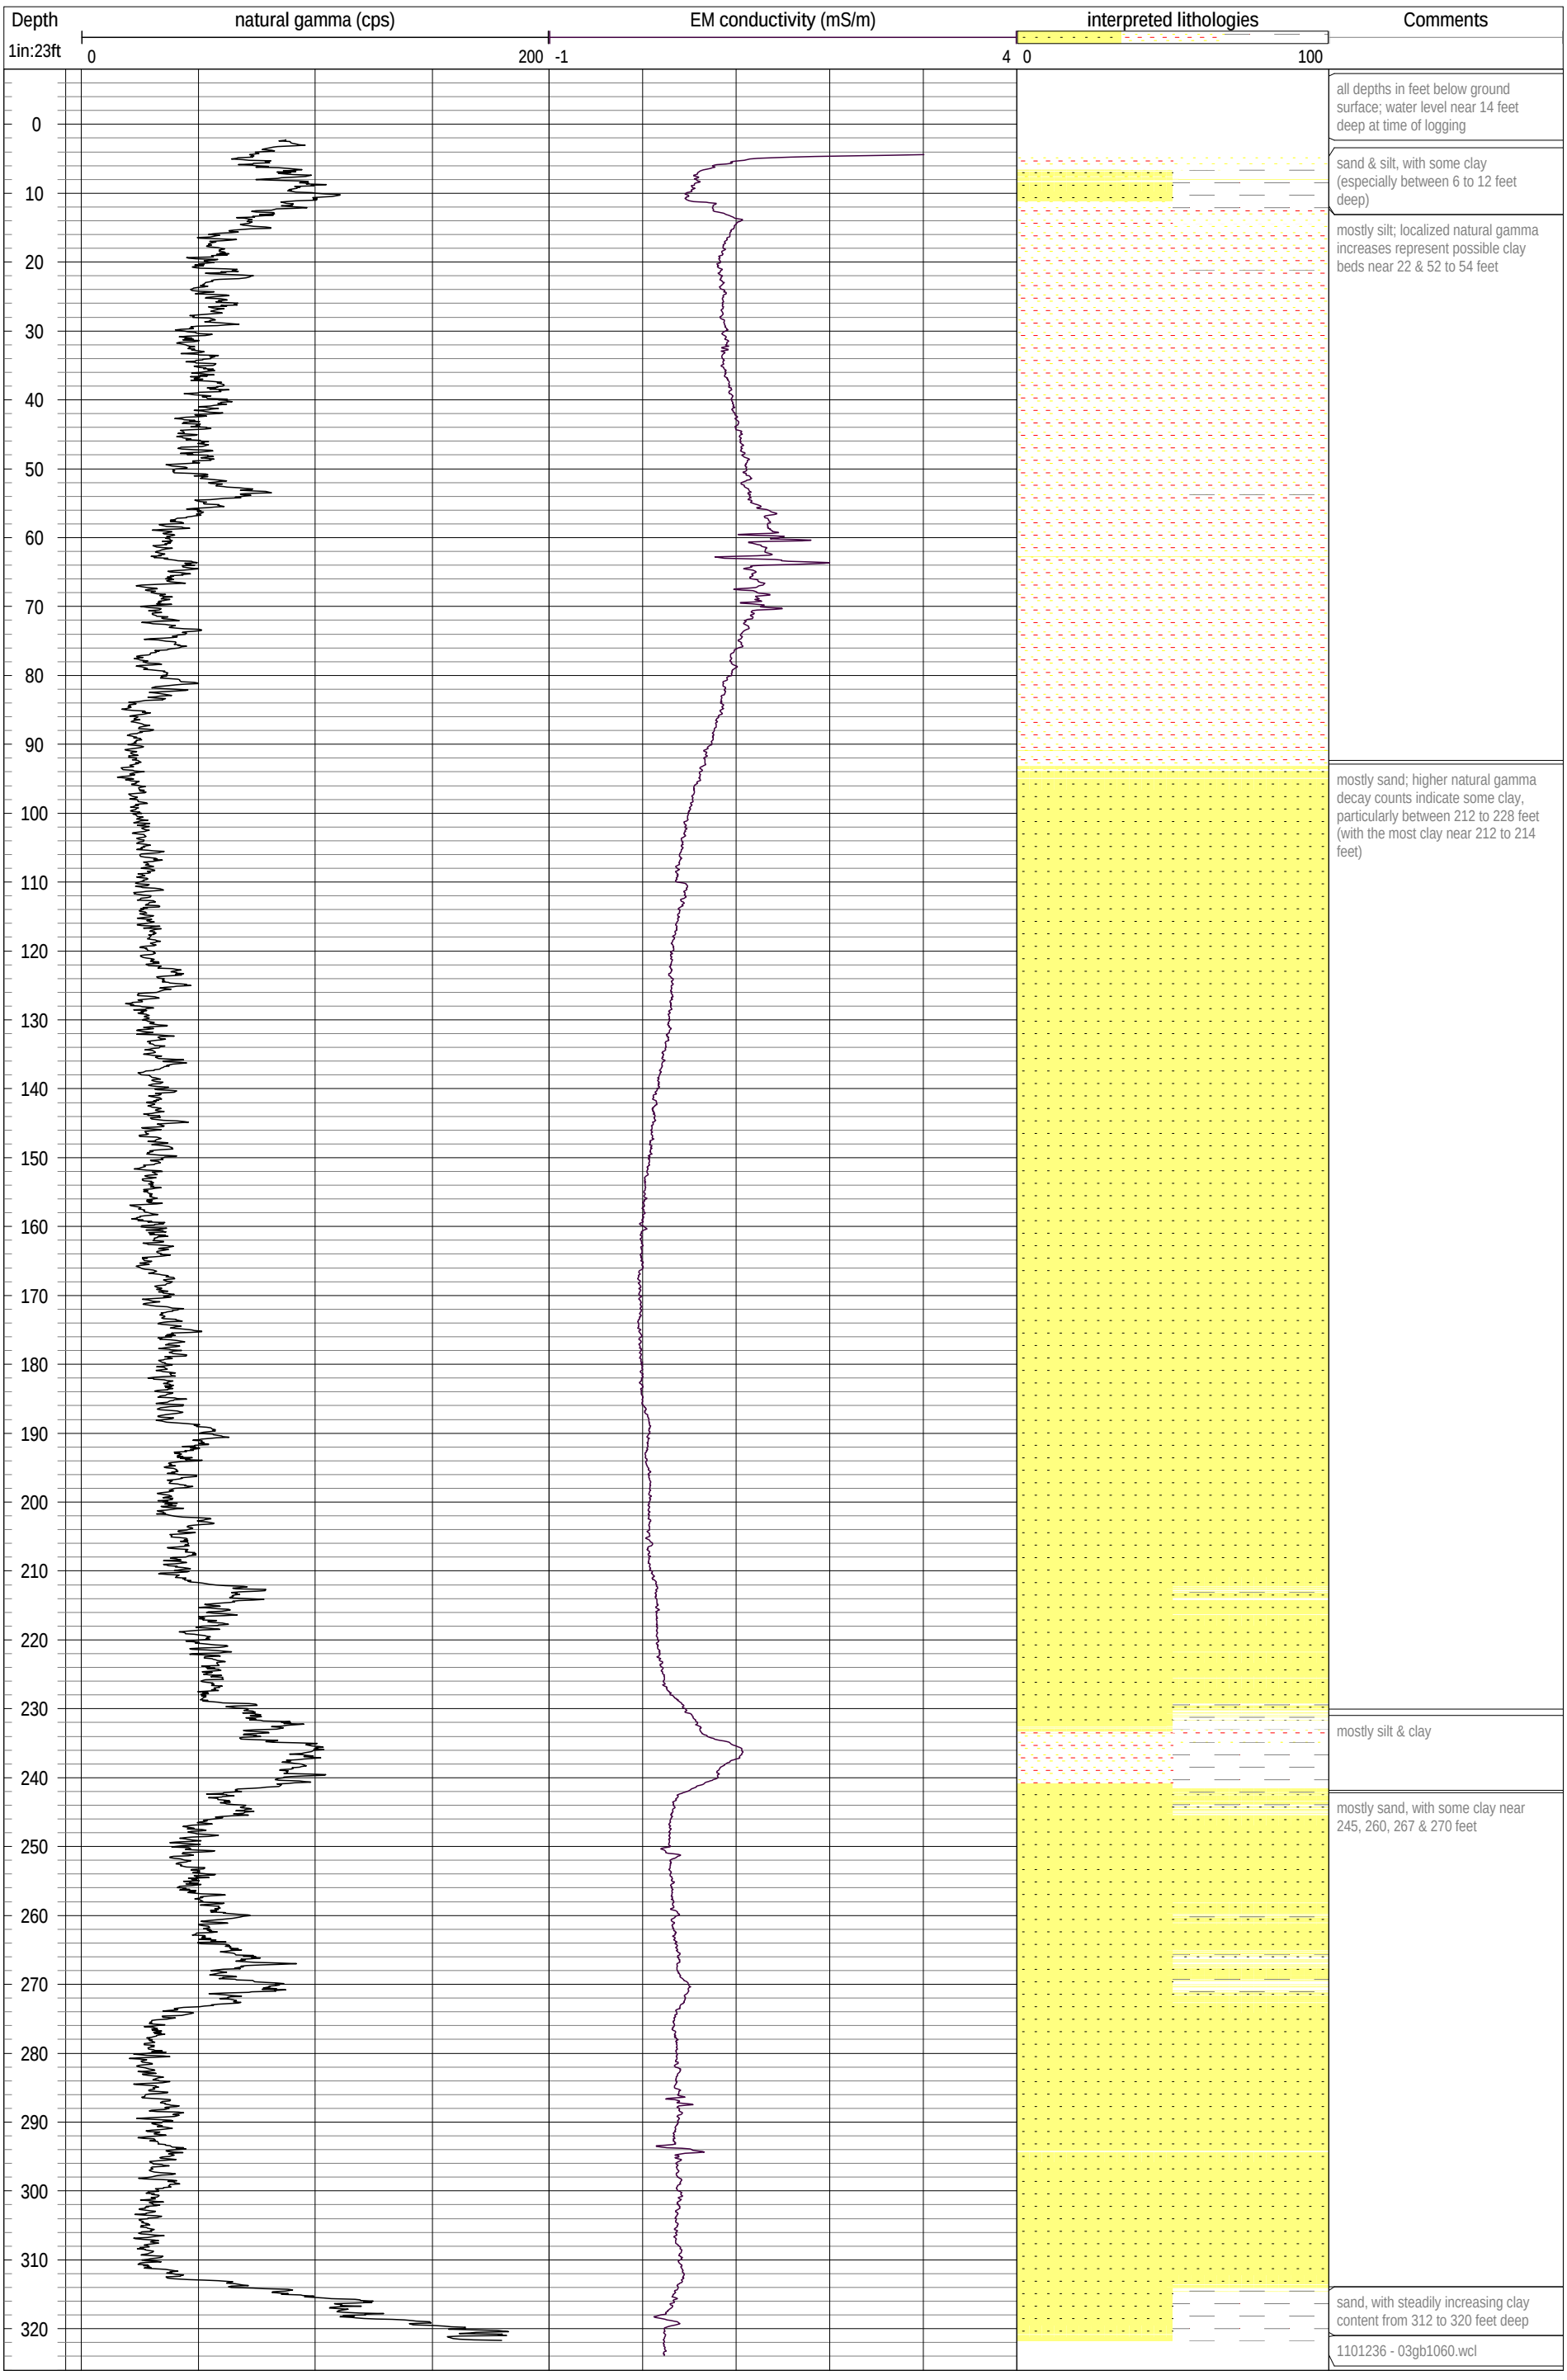
Note that the natural gamma logs may depict more-subtle variations in clay mineral content than can be ascertained from split-spoon samples alone. Consequently, some clayey layers inferred from the natural gamma logs may not have been visibly observed and noted on lithologic descriptions prepared when these wells were originally drilled.

Also note the generally similar natural gamma log patterns below 205 to 216 feet deep at each of the three logged wells. These similar natural gamma increases may represent a marker unit that correlates between: 212 feet deep at well 03GB1060, 205 feet deep at well 03MW1064A, and 216 feet deep at well 03MW1-67A.

The example drilling log provided for well 03MW1067A primarily included thick sections of sand (except for some sand and silt layers that were deeper than the logged well). If either of the other two wells encountered more variability (especially some thick silt layers within the geophysically-logged depth range), that might provide a better basis for comparison with the natural gamma and EM conductivity logs.

We appreciate this opportunity to provide geophysical services, and we welcome questions concerning this report. Please call the undersigned at 508/429-2430 if we may provide additional information that would benefit CH2M Hill's project.

Sincerely,



GEOPHYSICAL APPLICATIONS, INC.
